AP3776B

LOW POWER OFF-LINE PRIMARY SIDE REGULATION CONTROLLER

Description

The AP3776B is a high-performance AC/DC power supply controller for battery charger and adapter applications. It can meet less than 10mW standby power for "Super Star" charger criteria. The device uses pulse frequency modulation (PFM) method to build discontinuous conduction mode (DCM) flyback power supplies.

The AP3776B provides accurate constant voltage (CV), constant current (CC) and outstanding dynamic performance without requiring an optocoupler. It also eliminates the need of loop compensation circuitry while maintaining stability.

The AP3776B achieves excellent regulation and high average efficiency, less than 10mW no-load power consumption and less than 1s startup time. When AP3776B is used with AP4341, APR343 or APR3415, good under-shoot performance and higher conversion efficiency can be achieved.
The AP3776B is available in SO-8 package.

SO-8

Applications

- Adapters/chargers for shavers, cells/cordless phones, PDAs, MP3s and other portable apparatus
- Standby and auxiliary power supplies

Features

- Primary Side Control for Eliminating Optocoupler
- 10mW No-load Input Power
- Compensation for External Component Temperature Variations
- Flyback Topology in DCM Operation
- Random Frequency Adjustment to Reduce System EMI
- Semi-valley Turn on for the Higher Efficiency
- Built-in Soft Start
- Overvoltage Protection
- Overtemperature Protection
- Short-Circuit Protection
- AP4341, APR343 or APR3415 Awaking Signal Detection
- Audio Noise Reduction
- Internal Cable Compensation
- SO-8 Package
- **Totally Lead-Free & Fully RoHS Compliant (Notes 1 & 2)**
- **Halogen and Antimony Free. "Green" Device (Note 3**)
- **For automotive applications requiring specific change control (i.e. parts qualified to AEC-Q100/101/104/200, PPAP capable, and manufactured in IATF 16949 certified facilities), please contact us or your local Diodes representative. https://www.diodes.com/quality/product-definitions/**

Notes: 1. No purposely added lead. Fully EU Directive 2002/95/EC (RoHS), 2011/65/EU (RoHS 2) & 2015/863/EU (RoHS 3) compliant.
2. See https://www.diodes.com/quality/lead-free/ for more information about Diodes Incorporated's definitions of Halogen- and Antimony-free, "Green" and Lead-free.
3. Halogen- and Antimony-free "Green" products are defined as those which contain <900ppm bromine, <900ppm chlorine (<1500ppm total Br + Cl) and <1000ppm antimony compounds.

Function Description

Operation Description

1. Startup Circuit
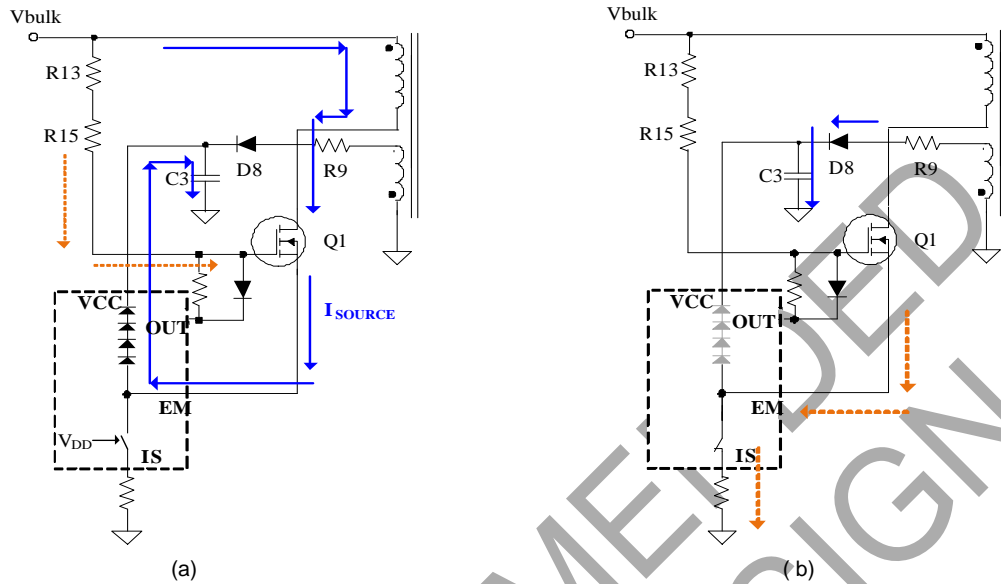

Figure 1. The AP3776B Startup Circuit

Figure1 (a) shows the startup phase

- Before V_{CC} reaches $V_{TH}(ST)$, V_{DD} is zero and EM to IS pin is open.
- C3 is charged by I_{SOURCE}.
- The resistance of R13 and R15 should be big enough to reduce the power dissipation.

Figure1 (b) shows the normal operation phase

- When V_{CC} reaches $V_{TH}(ST)$, V_{DD} is high and EM to IS pin is short.
- The voltage of EM pin is lower than 1V so that the four diodes in chip are open.
- C3 is supplied by Aux. winding of transformer.

2. Operation Mode

The typical application circuit of AP3776B is a conventional flyback converter with a 3-winding transformer---primary winding (N_P), secondary winding (N_S) and auxiliary winding (N_{AUX}), as shown in the figure of Typical Application of AP3776B with AP4341. The auxiliary winding is used for providing VCC supply voltage for IC and sensing the output voltage feedback signal to FB pin.

Figure 2 shows the typical waveforms which demonstrate the basic operating principle of AP3776B application. And the parameters are defined as following.

- I_P---The primary side current
- I_S ---The secondary side current
- I_{PK}---Peak value of primary side current
- I_{PKS}---Peak value of secondary side current
- V_{SEC}---The transient voltage at secondary winding
- V_S---The stable voltage at secondary winding when rectification diode is in conducting status, which equals the sum of output voltage V_{OUT} and the forward voltage drop of diode
- V_{AUX}---The transient voltage at auxiliary winding
- V_A--- The stable voltage at auxiliary winding when rectification diode is in conducting status, which equals the sum of voltage V_{CC} and the forward voltage drop of auxiliary diode
- t_{SW} ---The period of switching frequency
- t_{ONP} ---The conduction time when primary side switch is "ON"
- t_{ONS} ---The conduction time when secondary side diode is "ON"
- t_{OFF} ---The dead time when neither primary side switch nor secondary side diode is "ON"
- t_{OFFS} --- The time when secondary side diode is "OFF"

Function Description (continued)

Figure 2. The Operation Waveform of Flyback PSR System

For primary-side regulation, the primary current ip(t) is sensed by a current sense resistor R_{CS} (R5, R6 as shown in Typical Application of AP3776B). The current rises up linearly at a rate of:

$$\frac{dip(t)}{dt} = \frac{\text{Vin}(t)}{L_M} \qquad (1)$$

As illustrated in Figure 2, when the current ip(t) rises up to I_{PK}, the switch Q1 turns off. The constant peak current is given by:

$$I_{PK} = \frac{V_{CS}}{R_{CS}} \qquad (2)$$

The energy stored in the magnetizing inductance L_M each cycle is therefore:

$$Eg = \frac{1}{2} \times L_M \cdot I_{PK}^2 \qquad (3)$$

So the power transferring from the input to the output is given by:

$$P = \frac{1}{2} \times L_M \times I_{PK}^2 \times f_{SW} \qquad (4)$$

Where, the f_{SW} is the switching frequency. When the peak current I_{PK} is constant, the output power depends on the switching frequency f_{SW}.

The maximum frequency for AP3776B system is about 84kHz.

Constant Voltage Operation

As to constant voltage (CV) operation mode, the AP3776B detects the auxiliary winding voltage at FB pin to regulate the output voltage. The auxiliary winding voltage is coupled with secondary side winding voltage, so the auxiliary winding voltage at secondary rectification diode D1 conduction time is:

$$V_{AUX} = \frac{N_{AUX}}{N_S} \times (V_{OUT} + Vd) \qquad (5)$$

Where the Vd is the diode forward voltage drop.

## Function Description (continued)

Figure 3. Auxiliary Voltage Waveform

The voltage detection point is at 2/3 of the D1 on-time. The voltage detection point is changed with the different primary peak current. The CV loop control function of AP3776B then generates a D1 off-time to regulate the output voltage.

Constant Current Operation

The AP3776B can work in constant current (CC) mode. Figure 2 shows the secondary current waveforms.

In CC operation mode, the CC control loop of AP3776B will keep a fixed proportion between D1 on-time Tons and D1 off-time Toffs. The fixed proportion is

$$\frac{Tons}{Toffs} = \frac{4}{4} \qquad (6)$$

The relationship between the output current and secondary peak current I$_{PKS}$ is given by:

$$I_{OUT} = \frac{1}{2} \times I_{PKS} \times \frac{Tons}{Tons + Toffs} \qquad (7)$$

As to tight coupled primary and secondary winding, the secondary peak current is

$$I_{PKS} = \frac{N_P}{N_S} \times I_{PK} \qquad (8)$$

Thus the output constant-current is given by:

$$I_{OUT} = \frac{1}{2} \times \frac{N_P}{N_S} \times I_{PK} \times \frac{Tons}{Tons + Toffs} = \frac{2}{8} \times \frac{N_P}{N_S} \times I_{PK} \qquad (9)$$

Therefore, AP3776B can realize CC mode operation by constant primary peak current and fixed diode conduction duty cycle.

Multiple Segment Constant Peak Current

As to the original PFM PSR system, the switching frequency decreases with output current decreasing, which will encounter audible noise issue since switching frequency decrease to audio frequency range, about less than 20kHz.

In order to avoid audible noise issue, AP3776B uses 3-segment constant primary peak current control method. At constant voltage mode, the current sense threshold voltage is multiple segments with different loading, as shown in Figure 4, which are V$_{CS\_H}$ for high load, V$_{CS\_M}$ for medium load and V$_{CS\_L}$ for light load. At constant current mode, the peak current is still V$_{CS\_H}$. As to no load and ultra light load condition (LL mode), the current reference is also V$_{CS\_L}$. But the LL mode operating is different, which will be described in next section.

It can be seen from the following Figure 4 that with multiple segment peak current control, AP3776B power system can keep switching frequency above 24kHz from light load to heavy load and guarantee the audible noise free performance.
Function Description (continued)

Figure 4. Multiple Segment Peak Current at CV Mode

3. The LL Mode Operating (Typical Application with APR343)

At no load and light load, the AP3776B works in Low Light mode (LL mode) and the output voltage is detected by APR343. In order to achieve ultra-low standby power in LL mode, the static current (I_{CC_NL}) of the AP3776B is reduced from 280µA to 100µA.

• The conditions of exiting LL mode---V_{CPC}>65mV or t_{OFF}<t_{DELAY}+30µs

• The conditions of entering LL mode---V_{CPC}<33mV and t_{OFF}≥t_{DELAY}+30µs

In LL mode, when the APR343 detects the output voltage is lower than its trigger voltage, the APR343 VDET pin emits a periodical pulse current. This pulse current will generate a pulse voltage on feedback winding through the transformer coupling. When the AP3776B detects this V_{PULSE} (>100mV is valid), primary switch immediately turns on to provide one energy pulse to supply output terminal and primary V_{CC}. To achieve low standby power, the lower switching frequency is necessary. But if the off time is too long, the VCC voltage will reduce to very low level. To avoid V_{CC} being lower than V_{OPR}(Min), a minimum switching frequency is specified by the APR343 (t_{DIS}). If V_{OUT} does not fall below trigger voltage during t_{DIS}, APR343 VDET pin will emit the periodical pulse current and let the primary switch turn on.

4. Leading Edge Blanking

When the power switch is turned on, a turn-on spike will occur on the sense-resistor. To avoid false-termination of the switching pulse, a 500ns leading edge blanking (from power MOSFET on) is built in. During this blanking period, the current sense comparator is disabled and the gate driver can't be switched off.

5. Adjustable Line Compensation

Since there is a constant delay time from the CS pin voltage reaching the given V_{CS} reference to the power MOSFET turning off, the real primary peak current value always has a gap with the ideal value. The gap value changes with different input line voltage, which is caused by different current rising slope, results in different system constant current value.

In order to eliminate the constant current deviation due to line voltage, the adjustable line compensation is introduced to AP3776B design. By sensing the negative voltage of FB pin which is linear to the line voltage, a current (I_{LINE}) proportional to line voltage flows out from the CS pin to the resistor R_{LINE}, and create an adjustable compensation voltage to clear up the primary current gap, so that the excellent line regulation of output current will be achieved.

$$V_{CS\_LINE} = R_{LINE} \cdot 0.4 \cdot \frac{1}{700k} \cdot \frac{R_{FB2}}{R_{FB1} + R_{FB2}} \cdot \frac{N_{aux}}{N_p} \cdot V_{indc}$$

## Function Description (continued)

Figure 5. Adjustable Line Compensation Circuit

6. Fixed Cable Compensation

As we know, CPC voltage reflects the power system loading percentage. By introducing a rising voltage, which is linear to CPC voltage, to the FB reference voltage, AP3776B can realize the fixed cable compensation to match the voltage drop at output cable.

Protection

1. FB Overvoltage Protection (OVP)

When the voltage of FB pin exceeds $V_{FB}(OVP)$ at Tons period, AP3776B immediately shuts down for $t_{OFF}(MAX)$ and then detects the FB voltage again to see if $V_{FB}(OVP)$ condition is removed. The V_{CC} voltage will drop during the $t_{OFF}(MAX)$. When V_{CC} is still higher than $V_{OPR}(Min)$ after $t_{OFF}(MAX)$, and $V_{FB}(OVP)$ condition is removed, the IC will enter normal operating mode; but if $V_{FB}(OVP)$ condition is not removed, AP3776B will remain shutdown and wait for another $t_{OFF}(MAX)$. When V_{CC} drops to $V_{OPR}(Min)$ during the $t_{OFF}(MAX)$, AP3776B will enter the restart mode, and VCC voltage changes between $V_{TH}(ST)$ and $V_{OPR}(Min)$ until $V_{FB}(OVP)$ condition is removed.

2. Open-Circuit Protection (OCKP)

If the down resistance of FB pin short or up resistance open, there will be no voltage on FB pin, so the sample signal can't be monitored, and the OCKP protection will be triggered. The protection operating process is the same as overvoltage protection process.

3. Short-Circuit Protection (SCP)

Short-Circuit Protection (SCP) detection principle is similar to the normal output voltage feedback detection by sensing FB pin voltage. When the detected FB pin voltage is below $V_{FB}(SCP)$ for a duration of about $t_{OFF}(MAX)$, the SCP is triggered. Then the AP3776B enters hiccup mode that the IC immediately shuts down and then restarts, so that the VCC voltage changes between $V_{TH}(ST)$ and $V_{OPR}(Min)$ until $V_{FB}(SCP)$ condition is removed.

As to the normal system startup, the time duration of FB pin voltage below $V_{FB}(SCP)$ should be less than $t_{OFF}(MAX)$ to avoid entering SCP mode. But for the output short condition or the output voltage below a certain level, the SCP mode should happen.

Figure 6 shows the AP3776B normal startup waveform. If the voltage of FB pin reaches above $V_{FB(SCP)}$ during $t_{OFF}(MAX)$ after V_{CC} gets to the $V_{TH}(ST)$, the IC doesn't enter the SCP mode. Figure 7 shows that V_{OUT} is short and the voltage of FB pin is lower than $V_{FB(SCP)}$ during $t_{OFF}(MAX)$, then the AP3776B triggers the SCP and enters the hiccup mode.
Function Description (continued)

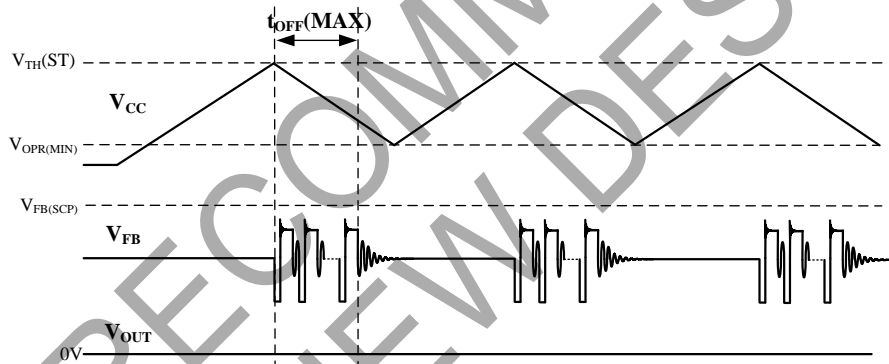

Figure 6. Normal Startup

Figure 7. Short-Circuit Protection (SCP) and Hiccup Mode

4. R_{CS} Short Protection

When the primary side current sense resistance is shorted, the primary side current rapidly increases, and the transformer saturates, which leads to some components' damage. The AP3776B draws in the R_{CS} short protection to avoid the damage. If the voltage of CS pin is smaller than 0.15V at the primary side maximum on-time tonp(MAX), the R_{CS} short protection is triggered, and the AP3776B immediately shuts down, and then restarts.

### 5. Overtemperature Protection (OTP)

When the IC junction temperature exceeds the thermal shutdown temperature threshold of +130ºC, the device shuts down immediately. Retry is allowed if junction temperature reduces by hysteresis temperature value.
