## 1 INTRODUCTION

The DIODES PI7C9X3G1224GP is a PCIe<sup>®</sup> GEN3 packet switch that supports 24 lanes of GEN3 SERDES in flexible 3-port to 12-port configurations. The architecture of the PCIe packet switch allows the flexible port configuration by allocating variable lane width for each port. A basic cell of the switch architecture is called a tile, which consists of 8 ports and 16 lanes for Tile 0, 4 ports and 8 lanes for Tile 1. The PI7C9X3G1224GP is built with 2 tiles connected by internal signal paths. Each tile can be configured to have different port types such as upstream port and downstream ports to support various port configurations for fan-out application in single switch or dual-switch partition modes. Besides fan-out, there are some designated ports can be programmed as Cross-Domain End-Point (CDEP) ports to allow multiple hosts connected to the switch for fail-over or multiple-host computation and communication applications. Inside the packet switch, multiple DMA channels are embedded to facilitate data communication more efficiently among hosts

In addition, the PI7C9X3G1224GP offers some extra benefits such as “maintaining high signal integrity in stress channel”, “advanced power management mechanism”, “enhanced reliability, availability and serviceability (RAS)” and “Surprised Hot Plug with LED Enclosure Management”.

## 2 GENERAL DESCRIPTION

Similar to the role of PCI/PCIX Bridge in PCI/PCIX bus architecture, the basic function of PCI Express (PCIe) Switch is to expand the connectivity to allow more end devices being reached by host controllers in terms of PCIe serial interconnect architecture. This 24-lane and 12-port PCIe Switch can extend the connections ranged from 3 to 12 PCIe devices by means of its flexible port and lane configurations. It provides users the variety to expand or fan-out the PCI Express lanes from one host based upon their application needs.

In PCI Express system bus hierarchy, the packet switch can be visualized as a logical assembly of multiple virtual PCI-to-PCI Bridge (PPB), which represents either upstream or downstream port. Also, normally all of the primary buses of downstream ports and secondary bus of upstream port are shared with one common virtual PCI Bus. In terms of the port configuration setting in a single host environment, the packet switch PI7C3G1224GP, which is constructed with 2 tiles, can be enumerated with one upstream-port PPB and up to 7 downstream-port PPBs in Tile 1 and 4 downstream-port PPBs in Tile 2. Then, the switch can be further discovered in another tile with one additional virtual downstream-port PPB cascaded with one virtual upstream-port PPB and up to 4 additional downstream-port PPBs under the virtual upstream-port PPB. Alternatively, in Switch Partition Mode, PI7C3G1224GP can be viewed as two independent PCI bus hierarchies in two different host domains. In Tile 0, bus hierarchy contains one upstream-port PPB and up to 7 downstream-port PPB's. In Tile 1, bus hierarchy contains one upstream-port PPB and up to 3 downstream-port PPB's.

The chip adopts hybrid architecture of Multiple-Ring and Network-on-Chip (NOC) as a switch core for reaching each individual port. There are 8 physical ports attached to one multiple-ring, which is a basic cell of switch architecture, called a tile. Two tiles are connected to each other through NOC to expand into a 12-port packet switch. Each port employs the structure of Combined Input and Output Queue (CIOQ) for buffer management. The main reason for choosing CIOQ is that the required memory bandwidth of input queue equals the line rate of ingress port rather than increasing proportionally with port numbers as is the case of an output queue Switch. The CIOQ at each ingress port contains separate dedicated input queues to store posted data, non-posted requests and completion packets. The packets are arbitrated to the egress port based upon the ID or address carried in the packet header along with the PCIe transaction-ordering rules.

Packets can be forwarded in downstream, upstream or peer-to-peer direction concurrently. For the packets without ordering enforcement, they are permitted to pass over each other in cases where the addressed egress port is available to accept them. This can mitigate the issue of Head-Of-Line (HOL) blocking and also not affecting the operation of producer-consumer model, which is required to be retained to prevent from system hang-up problem. On the other hand, the replay buffer at each egress port (output queue) enhances data integrity by preserving the transmitted packets until the appropriate ACK is returned by the link partner. As the out-going packets can be stored in replay buffer, this can gain the maximum throughput and efficiency of the Switch. Another advantage of implementing CIOQ in PCIe Switch is that the credit announcement to the counterpart is simplified and streamlined in terms of the credit-based flow control protocol. The protocol requires that each ingress port maintains the credits independently without checking other ports' credit availability, which is otherwise required by pure output queue architecture.

The Switch supports several advanced features of latest PCI Express specification. They include Access Control Service (ACS), Multi-Cast, Atomic Operation, Alternate Routing ID (ARI) and Address Translation (AT) packet forwarding etc. ACS allows the host system to have more control on peer-to-peer switch traffic. This can be a critical requirement in virtual machine system. Multi-Cast is an extended capability of PCIe switch to facilitate posted packets forwarded to a group of downstream ports efficiently. The switch is also capable of being a routing element for Atomic Operation commands, which has the advantages of synchronization among multiple processors or multiple-thread environment. When ARI capability is turned on, the ID routing has an alternative interpretation on Device and Function numbers. The Function number can be increased from 3 bits to 8 bits. This allows the downstream port of packet switch forwarding packets with up to 256 Functions.

Up to three dedicated ports in PI7C9X3G1224GP can be programmed as Cross-Domain End Point (CDEP) ports to support packet forwarding among multiple hosts and end-point devices. When the port is in CDEP mode (i.e. CD port for abbreviation), it would isolate the address and ID spaces of one host from another host. If the packet issued from one host domain to another host domain passes through CD port, the packet switch will be responsible for translating address and ID

of packets in order to prevent resource conflicts among domains. Meanwhile, the CD port also provides several mechanisms to facilitate [inter-processor communication](#). CDEP mode is configured by EEPROM programming after power up.

PI7C9X3G1224GP supports embedded Direct Memory Access (DMA) capability to move data between two address locations that are set up via DMA channels. There are eight physical DMA channels implemented in PI7C9X3G1224GP and each physical channel can be shared by two virtual channels. So a total of 16 DMA channels can be enabled in the packet switch to allow 16 pairs of locations transferring data simultaneously. The DMA engine is configured and managed by a software driver running on the hosts connected to the upstream port or CD ports. In terms of the address locations and DMA ownership, the DMA engines can be used in a variety of applications such as device status collection, peer-to-peer host transfer and peer-to-peer end-point transfer etc.

## 4 FUNCTIONAL OVERVIEW

This chapter provides an overview of the PI7C9X3G1224GP's major functions.

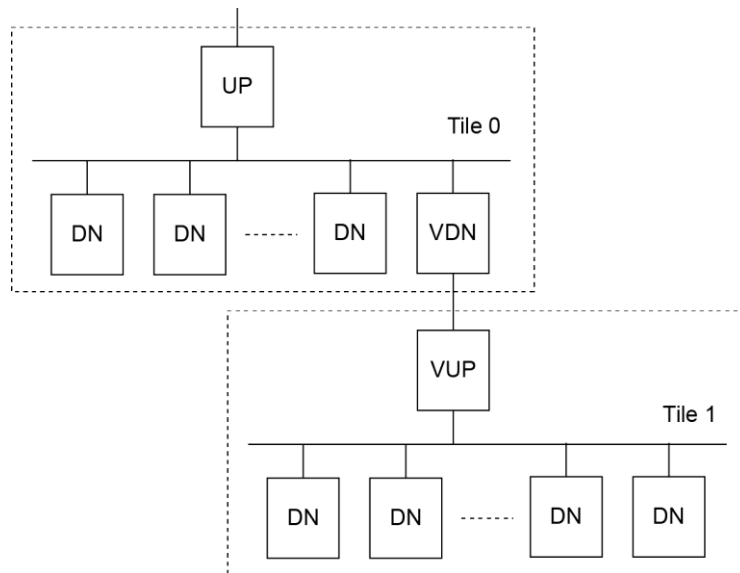

### 4.1 MODE OF OPERATIONS

The PI7C9X3G1224GP supports three modes of operations.

- Base Mode (Fan-out Mode)
- Switch Partition Mode (Fan-out Mode)
- Cross-Domain End-Point (CDEP Mode)

#### 4.1.1 BASE MODE (FAN-OUT MODE)

The Base mode is one of the Fan-out mode types. In this mode, the PI7C9X3G1224GP supports one upstream port and up to 15 down ports. Multiple virtual PCI-to-PCI bridges are connected by a virtual PCI bus, residing in the Switch.

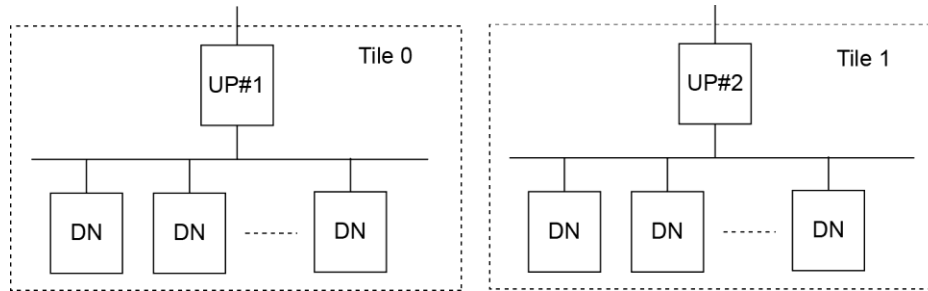

**Figure 4-1 Base Mode (Fan-out Mode) Overview**

#### 4.1.2 SWITCH PARTITION MODE (FAN-OUT MODE)

The Switch Partition mode is another type of the Fan-out mode. In this mode, the PI7C9X3G1224GP can be partitioned to two independent virtual switches. Each virtual switch has an independent PCI Express hierarchy, and the virtual switches do not share ports. There are two upstream ports, with one Root Complex attached to one upstream port, and a second Root Complex attached to a second upstream port.

**Figure 4-2 Switch Partition Mode (Fan-out Mode) Overview**

### 4.1.3 CROSS-DOMAIN END-POINT MODE

The switch supports a Cross-Domain End-Point (CDEP) mode allowing more than one host attached to PI7C9X3G1224GP. When configured as CDEP mode, one of downstream port will be turned into CDEP port for additional host to connect with it. So the packets produced from different hosts can exchange through PI7C9X3G1224GP [for system failover application.](#)

**Figure 4-3 Cross-Domain End-Point Mode Overview**

## 4.2 PHYSICAL LAYER CIRCUITS

The physical layer circuit design is defined as a converter between serial bus interface and the PHY Interface for PCI Express Architecture (PIPE). It contains Physical Media Attachment (PMA) and Physical Coding Sub-layer (PCS) blocks. PMA includes Serializer/ Deserializer (SERDES), PLL1, Adaptive TX and RX Equalization, Clock Recovery module, receiver detection circuit, electrical idle detector, and input/output buffers. PCS consists of two blocks for handling 128B/130B and 8B/10B encoder/decoder, SYNC code-word framer, receiver elastic buffer, and PIPE PHY control/status circuitries. To provide the flexibility for bifurcating multiple lanes into different port width of configuration, the control and status signals of each lane can be combined for MAC to access as a link basis. In addition, a pair of PRBS generator and checker is included for PHY built-in self-test. The main functions of physical layer circuits include the conversion between serial-link and parallel bus, provision of clock source for the Switch, resolving clock difference in receiver end, and detection of physical layer errors.

The driver characteristics including amplitude, and pre-emphasis, on transmit (TX) side are programmable. The PHY on receive (RX) side is capable of automatic calibration and configuration of the internal circuits to maximize receiving performance. In addition, the PHY provides the flexibility for user to override or disable the automatically calibrated settings.

Definition of the Switch Downstream Port's Transmitter presets can be set by LANE EQUALIZATION CONTROL REGISTER (OFFSET from 21Ch – 238h). The encoding for the Transmitter presets is provided in Table 4-1. The Transmitter Preset encoding of 1010b corresponds to the maximum Vtx-boost.

<sup>1</sup> Multiple lanes could share the PLL.

#### 4.2.1 PHY CONTROL REGISTER PARALLEL INTERFACE ACCESS

PI7C9X3G1224GP provides the flexibility for user to adjust the transmit swing through the Control Register (CR) Parallel register interface by PCIe link, EEPROM, SMBUS or I2C individually.

The PHY Control Register (CR) Parallel interface is a synchronous, 16 bit data/address parallel port provided for on-chip access to control registers inside the PHY. While access to these registers is not required for normal PHY operation, this interface is included for users that want to override some of the PHY's control signals.

The CR registers can be accessed through PCIe Configuration Registers. The user may access [CR RW CTRL and STATUS](#) register in PCIe Configuration Register space to access the PHY Control Register.

The PI7C9X3G1224GP is constructed of two tiles. Tile 0 is constructed of four PCIe PHYs to support 16 lanes, and Tile 1 is constructed of two PCIe PHYs to support 8 lanes. Each tile appears as a separate PCIe bridge device in the system with a single upstream port and multiple downstream port. The Tile ID can be located in [Operation Mode](#) register (Offset 348h[2:0]).

All PHY Registers of a given lane in any PHY can be configured through CR Parallel interface via PCI Configuration Registers in upstream port (Port 0): [CR RW CTRL AND STATUS](#) register (Port 0, Offset 5C0h), [CR CTRL 0](#) register (Port 0, Offset 5C4h), [CR CTRL 1](#) register (Port 0, Offset 5C8h), [CR CTRL 2](#) register (Port 0, Offset 5CCh) and [CR CTRL 3](#) register (Port 0, Offset 5D0h). The port is a upstream port when the Port Number field is 0 ([Link Capability](#) register, Offset 74h[31:24]),

The PHY Control Registers of any one of the 16 lanes in Tile 0 and 8 lanes in Tile 1 can be accessed through the CR CTRL register defined in the table below. A specific lane can be located by enumerating the PHY Number from 0 to 3 for Tile 0 and 0 or 2 for Tile 1, and the N Value from 0 to 3.

**Table 4-2 PCIe Configuration Registers Used to Access PHY CR Registers**

### 4.3 MEDIA ACCESS CONTROL (MAC)

The Media Access Control (MAC) block, which is consisted of physical layer packet boundary delineation and formation, multiple lanes de-skew, scrambler/de-scrambler, clock correction from inserting skip order-set, PIPE-related control/status circuits and Link Training Status State Machine (LTSSM), is implemented to interface physical layer with data link layer, build and maintain the link between two link partners.

The switch allows users to control GEN3 Link EQ parameters and link training behavior such as detection, compliance and lane reverse etc. The switch implements a group of LTSSM CSR registers located at offset starting from 380h to 3A0h to configure LTSSM operation.

### 4.4 DATA LINK LAYER (DLL)

The Data Link Layer (DLL) provides a reliable data transmission between two PCI Express points. An ACK/NACK protocol is employed to guarantee the integrity of the packets delivered. Each Transaction Layer Packet (TLP) is protected by a 32-bit LCRC for error detection. The DLL receiver performs LCRC calculation to determine if the incoming packet is corrupted in the serial link. If an LCRC error is found, the DLL transmitter would issue a NACK data link layer packet (DLLP) to the opposite end to request a re-transmission, otherwise an ACK DLLP would be sent out to acknowledge on reception of a good TLP.

The moment for issuing ACK DLLP is dependent on a time-out event of ACK latency timer or transmitter channel availability. According to PCI Express specification, the calculation of ACK latency timer is based upon maximum payload size, link width, TLP overhead, ACK factor and internal processing delay. The calculated values are determined by hardware as a default to meet PCIe specified requirement. On the other hand, the chip provides a flexibility to change the value of ACK latency timer by programming the bit 11 ~ bit 0 of DLL CSR registers at offset [420/424/428H](#) for G1/G2/G3 speed. The programmable ACK latency timer can regulate the frequency of issuing ACK DLLP. This can facilitate performance tuning under a burst of TLP in transmission.

In the transmitter, a retry buffer is implemented to store the transmitted TLPs whose corresponding ACK/NACK DLLP have not been received yet. When an ACK is received, the TLPs with sequence number equals to and smaller than that carried in the ACK would be flushed out from the buffer. If a NACK is received or no ACK/NACK is returned from the link partner after the replay timer expires, then a replay mechanism built in DLL transmitter is triggered to re-transmit the corresponding packet that receives NACK or time-out and any other TLP transmitted after that packet.

Meanwhile, the DLL is also responsible for the initialization, updating, and monitoring of the flow-control credit. All of the flow control information is carried in DLLP that is sent to the other end of link. Unlike TLP, DLLP is guarded by 16-bit CRC to detect if data corruption occurs. Furthermore, DLLP is used to handshake protocol between link parties for entering different power states such as PM L1.

The chip implements a group of DLL CSR registers started from offset [420h](#) to [46Ch](#) for users to control the Flow control packet behavior, DLL packet error status report, replay timer and ACK latency timer etc.

### 4.5 TRANSACTION LAYER RECEIVE BLOCK (TLP DECAPSULATION)

The receiving portion of the transaction layer performs header information retrieval and validates the correctness of the transaction type and format. If the TLP is found to contain an illegal header or the indicated packet length mismatches with the actual packet length, then a Malformed TLP is reported as an error associated with the receiving port. PCIe also supports End-to-End CRC operation to ensure end-to-end data integrity, a 32-bit ECRC is checked against the TLP at the receiver if the digest bit is set in header. Please note for ECRC operation, it is necessary both of EP and RC to support ECRC as well.

## 4.6 ROUTING

The transaction layer implements three types of routing protocols: ID-based, address-based, and implicit routing. For configuration reads, configuration writes, transaction completion, and user-defined messages, the packets are routed by their destination ID constituted of bus number, device number, and function number. Address routing is employed to forward I/O or memory transactions to the destination port, which is located within the address range indicated by the address field carried in the packet header. The packet header indicates the packet types including memory read, memory write, IO read, IO write, Message Signaling Interrupt (MSI) and user-defined message. Implicit routing is mainly used to forward system message transactions such as virtual interrupt line, power management, and so on. The message type embedded in the packet header determines the routing mechanism.

If the incoming packet cannot be forwarded to any other port due to a miss to hit the desired address range or targeted ID, this is considered as Unsupported Request (UR) packet, which is similar to a master abort event in PCI protocol.

In addition to following standard packet routing rule, the chip also implements a group of TL CSR registers started from offset [4C0h](#) to [4D0h](#) for users to control packet forwarding mode, packet ordering and arbitration scheme etc.

## 4.7 QUEUE

Six TLP packet types are defined in PCI Express architecture: Memory read/write, IO read/write, Config read/write, Completions, Messages, and Atomic. Each of these packet types fits into the separate switch queues: Posted Request Header (PH), Posted Request Data payload (PD), Non-Posted Request Header (NPH), Non-Posted Data Payload (NPD), Completion Header (CPLH) and Completion Data payload (CPLD). Each packet with different type would be put into a separate queue in order to facilitate the following ordering processor. NPD only contains one DW for all Non-post requests except CAS AtomicOP with 128-bit operand size, which requires two DWs, so it can be merged with the corresponding NPH into a common queue named NPHD.

### 4.7.1 POSTED REQUEST HEADER (PH)

PH queue provides TLP header spaces for posted memory writes and various message request headers. The types of TLP stored in this queue are MW<sub>r</sub>, Msg and Msg<sub>D</sub>. Each header space occupies sixteen bytes to accommodate 3 DW or 4 DW headers. The number of entries in PH range from 8 to 32 depending on the lane width of link.

### 4.7.2 POST REQUEST DATA (PD)

PD queue is used for storing posted request data. If the received TLP is a posted request type such as MW<sub>r</sub> or Msg<sub>D</sub>, and contained payload other than the header, the payload data would be put into PD queue. The size of PD queue ranges from 2KB to 8KB depending on the lane width of link.

### 4.7.3 NON-POSTED REQUEST HEADER AND DATA (NPHD)

NPHD queue provides TLP header spaces for non-posted request packets, which include memory read, IO read, IO write, configuration read, configuration write and AtomicOP requests. The types of TLP stored in this queue are MR<sub>d</sub>, MR<sub>d</sub>Lk, IOR<sub>d</sub>, IOW<sub>r</sub>, CfgR<sub>d</sub>0/CfgR<sub>d</sub>1, CfgW<sub>r</sub>0/CfgW<sub>r</sub>1, FetchAdd, Swap and CAS. Usually only IO or configuration write and Atomic requests are given additional data credit. The other TLP type is just given header credit. Each header space takes twenty-four bytes to accommodate the following combinations: 3-DW header, 4-DW header, 3-WD header with 1-DW data, 3-WD header with 2-DW data, 4-DW header with 1-DW data and 4-DW header with 2-DW data. In total, the number of entries in NPHD range from 8 to 32 depending on the lane width of link.

#### 4.7.4 COMPLETION HEADER (CPLH)

CPLH queue provides TLP header space for completion packets. The types of TLP stored in this queue are Cpl, CplD, CplLk and CplDLk. Each header space takes twelve bytes to accommodate a 3-DW header. Please note that there are no 4-DW completion headers. The number of entries in CPLH range from 8 to 32 depending on the lane width of link.

#### 4.7.5 COMPLETION DATA (CPLD)

CPLD queue is used for storing completion data. If the received TLP is a CplD or CplDLk type and contained payload other than the header, the payload data would be put into CPLD queue. The size of CPLD queues range from 2KB to 8KB depending on the lane width of link.

### 4.8 TRANSACTION ORDERING

A set of ordering rules is defined to regulate the transactions on the PCI Express Switch including Memory, IO, Configuration and Messages, in order to avoid deadlocks and to support the Producer-Consumer model. The ordering rules defined in Table 4-3 apply within a single Traffic Class (TC). There is no ordering requirement among transactions within different TC labels. Since the transactions with the same TC label are not allowed to map into different virtual channels, it implies no ordering relationship between the traffic in VC0.

**Table 4-3 Summary of PCI Express Ordering Rules**

Row Pass Column	Posted Request	Read Request	Non-posted Write Request	Read Completion	Non-posted Write Completion
Posted Request	Yes/No <sup>1</sup>	Yes <sup>5</sup>	Yes <sup>5</sup>	Yes <sup>5</sup>	Yes <sup>5</sup>
Read Request	No <sup>2</sup>	Yes	Yes	Yes	Yes
Non-posted Write Request	No <sup>2</sup>	Yes	Yes	Yes	Yes
Read Completion	Yes/No <sup>3</sup>	Yes	Yes	Yes	Yes
Non-Posted Write Completion	Yes <sup>4</sup>	Yes	Yes	Yes	Yes

1. When the Relaxed Ordering Attribute bit is cleared, the Posted Request transactions including memory write and message request must complete on the egress bus in the order in which they are received on the ingress bus. If the Relaxed Ordering Attribute bit is set, the Posted Request is permitted to pass over other Posted Requests occurring before it.
2. A Read Request transmitting in the same direction as a previously queued Posted Request transaction must push the posted write data ahead of it. The Posted Request transaction must complete on the egress bus before the Read Request can be attempted on the egress bus. The Read transaction can go to the same location as the Posted data. Posted read requests are not allowed to pass posted write transactions due to the concern that if the read and write are to the same location, the subsequent data returned from the read request would be stale data.
3. When the Relaxed Ordering Attribute bit is cleared, a Read completion must “pull” ahead of previously queued posted data transmitting in the same direction. In this case, the read data transmits in the same direction as the posted data, and the requestor of the read transaction is on the same side as the completer of the posted transaction. The posted transaction must deliver to the completer before the read data is returned to the requestor. If the Relaxed Ordering Attribute bit is set, then a read completion is permitted to pass a previously queued Memory Write or Message Request.
4. Non-Posted Write Completions are permitted to pass a previous Memory Write or Message Request transaction. Such transactions are actually transmitting in the opposite directions and hence have no ordering relationship.

- Posted Request transactions must be given opportunities to pass Non-posted Read and Write Requests as well as Completions. Otherwise, deadlocks may occur when some older bridges, which do Not support delayed transactions are mixed with PCIe Switch in the same system. A fairness algorithm is used to arbitrate between the Posted Write queue and the Non-posted transaction queue

## 4.9 PORT ARBITRATION

Among multiple ingress ports, the port arbitration built in the egress port determines which incoming packets to be forwarded to the output port. The arbitration algorithm the switch uses is fixed Round Robin. The port arbitration is held within the Virtual Channel 0. At the upstream ports, in addition to the inter-port packets, the intra-port packet such as configurations completion would also join the arbitration loop to get the service from Virtual Channel 0.

## 4.10 FLOW CONTROL

PCI Express employs Credit-Based Flow Control mechanism to make buffer utilization more efficient. The transaction layer transmitter ensures that it does not transmit a TLP to an opposite receiver unless the receiver has enough buffer space to accept the TLP. The transaction layer receiver has the responsibility to advertise the free buffer space to an opposite transmitter to avoid packet stale. In this Switch, each port has its own separate queues for different traffic types (Posted, Non Posted and Completion) and the credits of each type are continually updated via the data link layer on the fly. The data link layer compares the current available credits with the monitored ones and reports the updated credit to the counterpart. If no new credit is acquired, the credit reported is scheduled for every 30 us to prevent the link from entering retrain. On the other hand, the receiver at each egress port gets the usable credits from the opposite end in a link. The egress port notifies the usable credit information to all ingress ports to receive packets that are intended to that egress port.

## 4.11 TRANSACTION LAYER TRANSMIT BLOCK (TLP ENCAPSULATION)

The transmit portion of transaction layer performs the following functions. They construct the all types of forwarded TLP generated from VC arbiter, respond with the completion packets when the local resource (i.e. configuration register) is accessed, and regenerate the message that terminates at receiver to RC if acting as an upstream port.

## 4.12 ACCESS CONTROL SERVICE (ACS)

Traditionally, the packet routing between the peer-to-peer downstream ports is determined by either the address or ID field embedded in the packet header. Access Control Service (ACS) provides a mechanism for customer to selectively control access between PCI Express Endpoints attached to the downstream ports of packet switch. If ACS is enabled in the ingress port, the peer-to-peer packet forwarding will follow the rule sets of ACS rather than the destination ID or address. ACS is implemented as a set of capabilities and control registers in the associated hardware component. It brings the following benefits such as preventing the silent data corruption presented in Requests from being incorrectly routed to a peer Endpoint, validating every Request transaction between two downstream components and enabling direct routing of peer-to-peer Memory Requests whose addresses have been translated when ATS system is being used. ACS is usually enabled for directing all peer-to-peer traffic between downstream ports to upstream port.

Please refer to [ACS Extended Capability](#) registers at offset 1C0h for more information.

## 4.13 MULTICAST OPERATION

This is a PCIe optional feature allowing posted packets delivered to multiple endpoints with an efficient way. For some application, more than one target would receive the same packet. By using traditional unicast operation, this packet would be

repeatedly transmitted until all targets receive the same packet. The multicast operation would only require one-time transmission to serve all targets. The PCIe spec defines a Multicast Capability structure containing a Multicast address range that is dividable into multiple Multicast Group (MCG) with the size of Multicast Window to enable multicast operation. The multicast address range must be in the same host domain. Multicast is not translated into other host domain address location for cross-domain multicast transactions.

When the incoming packet hits the dedicated MCG within the Multicast address range defined in the ingress port, it will be simultaneously forwarded to the selected egress ports, which have the corresponding MCG bit set in MC\_Receive register, if no blocking happens in ingress port. The ingress port also allows the multicast-hit packet being dropped by enabling the corresponding MCG bit in MC\_Block\_All or MC\_Block\_Untranslated register.

Please refer to [Multicast Extended Capability](#) registers at offset 1D0h for more information.

### 5.1.3 PORT NUMBERING

There are two port numbering systems. One is the local numbering system and the other is the global numbering system. In the local numbering system, port number is given in the port number field of link capability register. Each port has a different link width capability, which is also defined in Maximum Link Width field of the capability register. The following table is the local port number in one tile and the corresponding maximum link width.

**Table 5-4 Port Numbering for Tile 0**

Port Number	P0	P1	P2	P3	P4	P5	P6	P7
Link Width	x8	x2	x4	x2	x8	x2	x4	x2

**Table 5-5 Port Numbering for Tile 1**

Port Number	P0	P1	P4	P5
Link Width	x4	x2	x4	x2

In the global port numbering system, the port number is formed by concatenating tile ID number and local port number, which results in a 6-bit wide of number such as (tile [2:0], port [2:0]).

### 5.1.4 PORT-LANE MAPPING

The table below shows the mapping of the lanes to ports in different functional modes.

Note: Switch supports automatic lane reversal within a port.

## 5.2 CLOCK SCHEME

### 5.2.1 REFERENCE CLOCK OPERATION MODES

The Switch supports two different reference clock operational modes defined by CKMODE. Each tile of the switch has its own CKMODE setting to allow flexible reference clock operation in various applications. If CKMODE is tied to “0”, the tile sourced from reference clocks is operating under BASE mode. If CKMODE is tied to “1”, the tile driven by reference clocks is operating under Cross Domain Separate Reference clock (CDSR) mode. The configured mode determines how the reference clock sources are connected to REFCLKP/N\_0[2:0] and REFCLKP/N\_1[1:0] input pins in each tile.

For example, when the Switch is configured to be in the BASE mode, all of the 16 lanes in tile 0 and 8 lanes in tile 1 are driven by REFCLKP/N\_0[2:0] and REFCLKP/N\_1[1:0]. In this mode, REFCLKP/N\_x[1] and REFCLKP/N\_0[2] are recommended to be connected to the ground. When the Switch is set to be in CDSR mode, the tile 0 allows three different reference clock sources to drive these 16 lanes and tile 1 allows two reference clock sources to drive these 8 lanes. The users can decide how the reference clocks are connected to the appropriate ports based on the appropriate port lane mapping.

When one of the tiles is configured to be in CDSR mode, the ports in the tile or chip operate in multiple reference clock domains. In this mode, some of ports work in one reference clock domain while others work in another domain. Each domain can turn on its own SSC function, and the Switch supports SSC isolation feature to allow ports in different SSC domains to transfer packets to each other correctly, given that the frequency differences are within 5600ppm.

The following table illustrates the connections of REFCLKP/N\_0[2:0] and REFCLKP/N\_1[1:0] in various use cases when CKMODE is set to BASE mode. The reference clock source comes from Root Complex (RC). The clock signal is distributed through buffer or generator to REFCLKP/N\_0[2:0] and REFCLKP/N\_1[1:0].

**Table 5-7 REFCLKP/N\_0[2:0] and REFCLKP/N\_1[1:0] connections when BASE mode is chosen**

Usage Case	REFCLK Architecture	REFCLKP/N_x[0]	REFCLKP/N_x[1]	REFCLKP/N_0[2]
Single Fan-out	Common/SRNS/SRIS	RC for all tiles (i.e. x = 0,1)	GND for all tiles (i.e. x = 0,1)	GND for tile 0
Switch Partition	Common/SRNS/SRIS	RC0 for tile 0 RC1 for tile 1	GND for all tiles (i.e. x = 0,1)	GND for tile 0

If CKMODE is set to CDSR, the use case is similar to multi-host domain. The REFCLK architecture is viewed as in SSC isolation. Each tile can be splitted into 2 host domains with the host port of P0 and P4. These two host ports can be linked at either x8 or x4 lane-width for Tile0, x4 lane-width for tile 1. The reference clock drives P0 via REFCLKP/N\_x[0], which is the main clock for the entire tile. In this mode, REFCLKP/N\_x[0] is isolated from REFCLKP/N\_x[1], which is connected to P4. REFCLKP/N\_x[0] and REFCLKP/N\_x[1] are sourced differently from the RC\_x in their own host domains. If Tile 0, P4 is linked at x4, the REFCLKP/N\_0[2] connects to the same source as REFCLKP/N\_0[0]. The following table illustrates the connection of REFCLKP/N\_0[2:0] and REFCLKP/N\_1[1:0] in SSC isolation condition.

**Table 5-8 REFCLKP/N\_0[2:0] / REFCLKP/N\_1[1:0] connections when CDSR mode is chosen**

Port 0	Port 4	REFCLKP/N_0[0]	REFCLKP/N_0[1]	REFCLKP/N_0[2]
x8 or x4	x8	RC_x[0]	RC_x[1]	GND for tile 0
x8 or x4	x4	RC_x[0]	RC_x[1]	RC_0[0]
Port 0	Port 4	REFCLKP/N_1[0]	REFCLKP/N_1[1]	
x4	x4	RC_x[0]	RC_x[1]	

## 5.2.2 INTEGRATED REFERENCE CLOCK BUFFER

The built-in Integrated Reference Clock Buffer of the PI7C9X3G1224GP supports eight reference clock outputs in each tile. Each tile has its strapping pin CKBUFPD<sub>x</sub>\_L to enable or disable the internal clock buffer feature.

When CKBUFPD<sub>x</sub>\_L pin is asserted high, the integrated reference clock buffer is enabled. The clock buffer distributes a single 100 MHz reference clock input to eight for tile 0 and four for tile 1 reference clock output pairs, REFCLKOP/N\_0[7:0] and REFCLKOP/N\_1[5,4,1,0]. The integrated reference clock buffer supports two different operation modes which set by CLKBUF\_CMOS\_EN<sub>x</sub>\_L pins. When CLKBUF\_CMOS\_EN<sub>x</sub>\_L set “1”, the integrated clock buffer requires 100 MHz differential clock inputs through REFCLKIP/N\_x pins as shown in Table 5-9. When CLKBUF\_CMOS\_EN<sub>x</sub>\_L set “0”, REFCLKIP/N\_x are recommended to be connected to the ground.

When CKBUFPD<sub>x</sub>\_L pin is asserted low, the integrated clock buffer is in power down mode and disabled. The 100 MHz reference clock output pairs are disabled.

The connection of REFCLKOP/N\_0[7:0] / REFCLKOP/N\_1[5:4,1:0] pins of PI7C9X3G1224GP and the reference clock input of downstream port devices have to follow the table shown below if L1.1 is implemented. Note that only tile 0 support L1.1 function.

When CKMODE is set to CDSR mode, REFCLKOP/N\_0[0] is un-used and REFCLKP/N\_0[2:0] are connected to external reference clock sources which need belong to the same clock buffer.

The REFCLKOP/N\_0[7:0] is not only enabled or disabled by a global control signal CKBUFPD0\_L, but also controlled by CLKREQ0\_L[7:0] pins and internal downstream-port device clock status individually based on L1 PM Substate rule. The output control signals for REFCLKOP/N\_0[7:0] are mapped as the following table.

**Table 5-10 Output Control for REFCLKOP/N\_0[7:0]**

Note: When CKMODE is set to BASE mode, REFCLKP/N\_0[0] can be connected to REFCLKOP/N\_0[0] or external reference clock source. When CKMODE is set to CDSR mode, REFCLKOP/N\_0[0] is un-used and REFCLKP/N\_0[2:0] are connected to external reference clock sources which need belong to the same clock buffer.

The CLKREQ0\_L[0] is an upstream control signal that should be connected from the switch output with external pull-up to the CLKREQ\_L pin on the host chip (Root Complex). The switch combines the CLKREQ0\_L[7:1] and CLKREQ1\_L[7:0] and drives the resulting signal out on the CLKREQ0\_L[0]. When endpoints do not have any packets to transmit, the switch and endpoints will not drive CLKREQ0\_L[7:1] and CLKREQ1\_L[7:0], CLKREQ0\_L[7:1] and CLKREQ1\_L[7:0] will be high due to external pull-up resistor and the reference clock REFCLKOP/N\_0[7:1] and REFCLKOP/N\_1[7:0] for down ports will stop. Then, the switch does not drive the CLKREQ0\_L[0] low on its upstream port. If the Root Complex does not have any packets requiring transmission, it does not drive the CLKREQ0\_L[0] either. In this case, the CLKREQ0\_L[0] will be high due to external pull-up resistor to stop the reference clock source for the upstream port.

If desires to disable some specified Reference Clock Output Paris, it can be done by Port Clock Enable field in the Bifurcation Control Register ([offset 55Ch](#).bit[31:24]) through I2C, SMBUS or EEPROM.

## 5.3 EEPROM INTERFACE

The EEPROM interface consists of four pins: EESK (EEPROM clock), EEDI (EEPROM serial data input), EEDO (EEPROM serial data output) and EECS (EEPROM chip select). The Switch supports 2-, or 3-byte address SPI EEPROM parts and automatically determines the appropriate addressing mode. The EEPROM is used to initialize a number of registers before enumeration. This is accomplished after PERST\_L is de-asserted, at which time the data from the EEPROM is loaded. The EEPROM interface is organized into a 16-bit base, and the Switch supplies an 8-bit EEPROM word address.

### 5.3.1 EEPROM ACCESS MODES

The Switch may access the EEPROM in a WORD format by either utilizing the auto mode through a hardware sequencer or interactive mode through the host configuration commands. For auto mode, it only happens during chip initialization after system reset (Please refer to 5.3.2 for more details). As to interactive mode, it allows to read/write data from/into the EEPROM by giving the command, address and data via EEPROM Control, address and data configuration registers at offset [308h](#) and [30Ch](#).

### 5.3.2 EEPROM MODE AT RESET

During a reset, the Switch automatically loads the information/data from the EEPROM if the automatic load condition is met. The first offset in the EEPROM contains a signature. If the signature is recognized, the autoloader initiates right after the reset.

During the autoloader, the Switch will read sequential words from the EEPROM and write to the appropriate registers. Before the Switch registers can be accessed through the host, the autoloader condition should be verified by reading bit [4] offset [308h](#) (EEPROM Autoloader Status). The host access is allowed only after the status of this bit is set to '1' which indicates that the autoloader initialization sequence is completed.

## 5.4 SMBUS INTERFACE

The Packet Switch provides the System Management Bus (SMBus), a two-wire interface through which a simple device can communicate with the rest of the system. The SMBus interface on the Packet Switch is a bi-directional slave interface. It can receive data from the SMBus master or send data to the master. The interface allows full access to the configuration registers. A SMBus master, such as the processor or other SMBus devices, can read or write to every RW configuration register (read/write register). In addition, the RO and HwInt registers (read-only and hardware initialized registers) that can be auto-loaded by the EEPROM interface can also be read and written by the SMBus interface. This feature allows increases in the system expandability and flexibility in system implementation.

**Figure 5-1 SMBus Architecture Implementation**

The SMBus interface on the Packet Switch consists of one SMBus clock pin ([SCL I2C](#)), a SMBus data pin ([SDA I2C](#)), and 3 SMBus address pins ([I2C ADDR\[2:0\]](#)). The SMBus clock pin provides or receives the clock signal. The SMBus data pin facilitates the data transmission and reception. Both of the clock and data pins are bi-directional. The SMBus address pins determine the address to which the Packet Switch responds to. The SMBus address pins generate addresses according to the following table:

**Table 5-12 SMBUS Address Pin Configuration**

BIT	SMBus Address For Tile 0	SMBus Address For Tile 1
0	I2C_ADDR[0]	I2C_ADDR[0]+1
1	I2C_ADDR[1]	I2C_ADDR[1]
2	I2C_ADDR[2]	I2C_ADDR[2]
3	1	1
4	0	0
5	1	1
6	1	1

Software can change the SMBus Slave address, by programming the SMBus/I2C Control Register SMBus/I2C Device Address field.

The Switch also supports Packet Error Checking and Packet Error Code (PEC) generation, as explained in the SMBus v2.0.

The Switch supports three commands:

- Block Write (command BEh) is used to write CFG registers

- Block Write (command BAh), followed by Block Read (command BDh), is used to read CFG registers
- Block Read - Block Write Process Call (commands BAh, CDh) can also be used to read CFG registers

### 5.4.1 SMBUS BLOCK WRITE

The Block Write command is used to write to the Switch registers. General SMBus Block Writes are illustrated in Figure 5-2 and Figure 5-3. Table 5-13 explains the elements used in Figure 5-2 and Figure 5-3.

**Figure 5-2 SMBus Block Write Command Format, to Write to a Switch Register without PEC**

**Figure 5-3 SMBus Block Write Command Format, to Write to a Switch Register with PEC**

Block Write transactions that are received with incorrect Cmd Code are NACKed, starting from the wrong byte setting, and including subsequent bytes in the packet. For example, if the Byte Count value is not 8, the Switch NACKs the byte corresponding to the Byte Count value, as well as any Data bytes following within the same packet.

The byte after Data Byte 4, if present, is taken as the PEC byte, and if present, the PEC is checked. If a packet fails Packet Error Checking, the Switch drops the packet (ignores the Write), and returns NACK for the PEC byte, to the SMBus Master. Packet Error Checking can be disabled, by setting the SMBus/I<sup>2</sup>C Control Register PEC Check Disable bit. The Byte Count value, by definition, does not include the PEC byte.

### 5.4.2 SMBUS BLOCK READ

A Block Read command is used to read Switch CFG registers. Similar to CFG register Reads using I<sup>2</sup>C, a SMBus Write sequence must first be performed to select the register to read, followed by a SMBus Read of the corresponding register. There are two ways a Switch register can be read:

- Use a Block Write, followed by a Block Read. The Block Write sets up the parameters including Port Number, register address and Byte Enables, and the Block Read performs the actual Read operation.
- Use a Block Read - Block Write Process Call. This command is defined by the SMBus v2.0, and performs a Block Write and Block Read, using a single command. The Block Write portion of the message sets up the register to be read, and then a repeated START followed by the Block Read portion of the message returns the register data specified by the Block Write

The Switch always NACKs any incorrect command sequences, starting with the wrong Byte. Upon receiving the Block Read command, the Switch returns a PEC to the Master, if after the 4th byte of register data, the Master still requests one more Byte. As a Slave, the Switch recognizes the end of the Master's Read cycle, by observing the Master's NACK response for the last Data Byte transmitted by the Switch.

Incorrect command sequences are always NACK, starting with the byte that is incorrect. (Refer to Table 5-15) On the Block Read command, a PEC is returned to the Master, if after the 4th byte of CSR data, the return Master still requests for one additional byte. As a Slave, the Switch will know the end of the Master Read cycle, by observing the NACK for the last byte read from the Master.

### 5.4.3 CSR READ, USING SMBUS BLOCK READ – BLOCK WRITE PROCESS CALL

A general SMBus Block Read - Block Write Process Call sequence is illustrated in Figure 5-5. Alternatively, a general SMBus Block Read - Block Write Process Call with PEC sequence is illustrated in Figure 5-6.

Using this command, the register to be read can be set up and read back with one SMBus cycle (a transaction with a START and ending in STOP). There is no STOP condition before the repeated START condition. The command format for the Block Write part of this command has the same sequence as in Table 5-16, except that the Command Code changes to CDh, as illustrated below. Other Bytes remain the same as used in the sequence for SMBus Block Write followed by Block Read.

Table 5-20 lists the Command format for Block Read.

## 5.5 I2C INTERFACE

Inter-Integrated Circuit (I<sup>2</sup>C) is a bus used to connect Integrated Circuits (ICs). Multiple ICs can be connected to an I<sup>2</sup>C Bus, and I<sup>2</sup>C devices that have I<sup>2</sup>C mastering capability can initiate a Data transfer. I<sup>2</sup>C is used for Data transfers between ICs at relatively low rates (100 Kbps), and is used in a variety of applications. For further details regarding I<sup>2</sup>C Buses, refer to the *I<sup>2</sup>C Bus v2.1*.

The Switch is an I<sup>2</sup>C Slave. Slave operations allow the Switch's Configuration Registers to be read from or written to by an I<sup>2</sup>C Master, external from the device. I<sup>2</sup>C is a sideband mechanism that allows the device Configuration registers to be programmed, read from, or written to, independent of the PCI Express upstream Link.

**Figure 5-7 Standard Devices to I2C Bus Connection Block Diagram**

The I<sup>2</sup>C interface on the Packet Switch consists of a I<sup>2</sup>C clock pin ([SCL\\_I2C](#)), a I<sup>2</sup>C data pin ([SDA\\_I2C](#)), and 3 I<sup>2</sup>C address pins ([I2C\\_ADDR\[2:0\]](#)). The I<sup>2</sup>C clock pin provides or receives the clock signal. The I<sup>2</sup>C data pin facilitates the data transmission and reception. Both of the clock and data pins are bi-directional. The I<sup>2</sup>C address pins determine the address to which the Packet Switch responds to. The I<sup>2</sup>C address pins generate addresses according to the following table:

**Table 5-21 I<sup>2</sup>C Address Pin Configuration**

BIT	I2C Address for Tile 0	I2C Address for Tile 1
0	I2C_ADDR[0]	I2C_ADDR[0]+1
1	I2C_ADDR[1]	I2C_ADDR[1]
2	I2C_ADDR[2]	I2C_ADDR[2]
3	1	1
4	0	0
5	1	1
6	1	1

Software can change the I<sup>2</sup>C Slave address, by programming the SMBus/I<sup>2</sup>C Control Register SMBus/I<sup>2</sup>C Device Address field.

### 5.5.1 I2C REGISTER WRITE ACCESS

The Switch Configuration registers can be read from and written to, based upon I<sup>2</sup>C register Read and Write operations, respectively. An I<sup>2</sup>C Write packet consists of Address Phase bytes and Command Phase bytes, followed by one to four additional I<sup>2</sup>C Data bytes. Table 5-22 defines mapping of the I<sup>2</sup>C Data bytes to the Configuration register Data bytes.

The I<sup>2</sup>C packet starts with the S (START condition) bit. Data bytes are separated by the A (Acknowledge Control Packet (ACK)) or N (Negative Acknowledge (NAK)) bit. The packet ends with the P (STOP condition) bit. If the Master generates an invalid command, the targeted Switch register is not modified. The Switch considers the 1st Data byte of the 4-byte Data phase, following the four Command bytes in the Command phase, as register Byte 3 (bit[31:24]). The next three Data bytes access register Bytes 2 through 0, respectively. Four Data bytes are required, regardless of the Byte Enable Settings in the Command phase. The Master can then generate either a STOP condition (to finish the transfer) or a repeated START condition (to start a new transfer). If the I<sup>2</sup>C Master sends more than the four Data bytes (violating Switch protocol), further details regarding J2C protocol, the Switch returns a NAK for the extra Data byte(s).

Table 5-23 describes each I<sup>2</sup>C Command byte for Write access. In the packet described in Figure 5-8, Command Bytes 0 through 3 for Writes follow the format specified in Table 5-23.

**Table 5-22 I2C Register Write Access**

### 5.5.2 I2C REGISTER READ ACCESS

When the I<sup>2</sup>C Master attempts to read a Switch register, two packets are transmitted. The 1<sup>st</sup> packet consists of Address and Command Phase bytes to the Slave. The 2<sup>nd</sup> packet consists of Address and Data Phase bytes.

According to the I<sup>2</sup>C Bus, v2.1, a Read cycle is triggered when the Read/Write bit (bit 0) of the 1<sup>st</sup> cycle is Set. The Command phase reads the requested register content into the internal buffer. When the I<sup>2</sup>C Read access occurs, the internal buffer value is transferred on to the I<sup>2</sup>C Bus, starting from Byte 3 (bit[31: 24]), followed by the subsequent bytes, with Byte 0 (bit[7:0]) being transferred last. If the I<sup>2</sup>C Master requests more than four bytes, the Switch re-transmits the same byte sequence, starting from Byte 3 of the internal buffer.

The 1<sup>st</sup> and 2<sup>nd</sup> I<sup>2</sup>C Read packets perform the following functions:

- 1<sup>st</sup> packet - Selects the register to read
- 2<sup>nd</sup> packet - Reads the register (sample 2<sup>nd</sup> packet provided is for a 7-bit Switch I<sup>2</sup>C Slave address)

Although two packets were shown for the I<sup>2</sup>C Read, the I<sup>2</sup>C Master can merge the two packets together into a single packet, by not generating the STOP at the end of the first packet (Master does not relinquish the bus) and generating REPEAT START.

Table 5-24 describes each I<sup>2</sup>C Command byte for Read access. In the packet described in Figure 5-11, command Bytes 0 through 3 for Reads follow the format specified in Table 5-24.

## 6 HOT PLUG SUPPORT

The hot plug usages can be classified into surprised and managed types depending on the application scenario. Each type has two different control and status interfaces: serial and parallel. The switch implements both surprised/managed and serial/parallel hot-plug types in the downstream ports. The [HOT PLUG EN0 L](#) and [HOT PLUG EN1 L](#) strapping pin should be set to “0” to enable hot plug function in the downstream ports of the switch.

### 6.1 HOT PLUG TYPES

#### 6.1.1 SURPRISED SERIAL HOT PLUG

If the device is inserted or removed asynchronously from downstream port, it is called surprised hot plug. When SURPRISE\_HP strapping pin is set to “1”, the chip is operating under surprised hot plug mode.

- Hot Insertion Procedures:
  - Present Detect Pin (i.e. PDC0\_L[7:0] or PDC1\_L[5,4,1,0] ) is asserted
  - The corresponding “Presence Detect Change” and “Present Detect State” in slot status reflect the card is in the slot
  - Enable the corresponding reference clock output (i.e. REFCLKOP/N\_0[7:0] or REFCLKOP/N\_1[5,4,1,0]) to the hot inserted device
  - Issue INTx Message or MSI to notify software processing hot plug event
  - Wait for 628ms and then deassert the corresponding downstream reset (i.e. HP0\_RST\_L[7:0] or HP1\_RST\_L[5,4,1,0])
  - If DL\_UP is set, then generating INTx Message or MSI to notify software initiating configuration cycles to the hot inserted device
- Hot Removal Procedures
  - The device is removed asynchronously or under abnormal condition (Ex. Human Error ...)
  - Either in-band or out-band Present Detect sensing device being removed
  - Commands LTSSM state machine to Detect.Quiet state
  - Upstream port replies UR status that any TLP being sent to this downstream port
  - Any packet stored in input queue of upstream port will be dropped silently
  - Assert Present detect change Interrupt to system software
  - Enable DPC trigger event and assert DPC interrupt and unmasked non-fatal message to system software
  - Turn off the corresponding output clock buffer and assert the corresponding hot plug reset signal

During power-up, the chip scans IO Expander like devices through I2C clock and data signals (i.e. SHCL\_I2C\_x and SHDA\_I2C\_x). According to the reference design described in LED management, one set of I2C bus serves 4 CPLD, which converts the serial bus into 8-bit parallel bus. The 8-bit mapping is defined in Table 6-1.

**Table 6-1 CPLD Signal Name Mapping for 8-bit IO Expander**

BIT	DIRECTION	CLD SIGNAL NAME
0	O	FAULT
1	O	LOCATE
2	N/A	Not used (Debug Only)
3	N/A	Not used (Debug Only)
4	I	PRSNT_L
5	N/A	Not used (Debug Only)
6	N/A	Not used (Debug Only)
7	N/A	Not used (Debug Only)

Among these signals, ATNLED and PWRLED defined in PCIe specification are repurposed to represent FAULT and LOCATE to be compliant with SFF-8489 for blinking LEDs. For details, please refer to LED Management specification.

The switch hot plug controller supports multiple I2C/SMBUS-like control interfaces. Each interface can serve up to 8 downstream ports. The I2C/SMBUS address for slave devices is started from 40h by default. In addition, this initial address is configurable through EEPROM to [LTSSM 2 Register, Bit\[30\]](#) and [LTSSM 3 Register, Bit\[6:0\]](#). Each downstream port is correspondent to one equivalent 8-bit IO expander with the following Port/Address mapping table.

**Table 6-2 Port/Address Mapping for 8-bit IO Expander**

Downstream Port Number	P1	P2	P3	P4	P5	P6	P7	P8
Address	40h	41h	42h	43h	44h	45h	46h	47h

### 6.1.2 SURPRISED PARALLEL HOT PLUG

The parallel mode of Surprised Hot Plug is very similar to its serial mode except that no CPLD is required to control LED. Instead, the chip outputs LED signals (i.e. HPx\_LED [7:0]) to drive Amber LED directly and the blinking follows SFF-8489 IBPI specification.

### 6.1.3 MANAGED SERIAL HOT PLUG

If the device is inserted or removed synchronously with hot-plug management software from downstream port, it is called managed hot plug. When SURPRISE\_HP strapping pin is set to “0”, the chip is operating under managed hot plug mode.

- Hot Insertion Procedures:
  - User inserts card
  - User closes MRL
  - User initiates hot-inserted sequence by pressing Attention Button
  - System commands slot control register to drive indicators and power on slot
  - System starts re-enumeration the hierarchy under the slot
- Hot Removal Procedures:
  - User initiates hot-removed sequence by pressing Attention Button
  - System informs application/driver to complete current task
  - System commands slot control register to drive indicators and power off slot
  - System disabled the hierarchy under the slot
  - User opens MRL and removes the card

During the process of hot insertion and removal, there are hot plug events corresponding to slot status bits ready for generation. When [Hot-Plug Interrupt Enable](#) bit is set, either MSI or INT message is issued to notify S/W for processing.

When power-up, the chip uses I2C clock and data signals to scan either 16-bit or 40-bit IO Expander dependent on the setting of [LTSSM 2 REGISTER – OFFSET 398h](#). The IO Expander responds an interrupt (i.e. [SHPCINTx\\_L](#)) to notify any hot plug signal status change and the chip will read back the status change in serial mode and reflect on slot status register. The 16-bit mapping of managed hot plug events for I2C bit sequence is defined in Table 6-3

**Table 6-3 CPLD Signal Name Mapping for 16-bit IO Expander**

BIT	DIRECTION	CLD SIGNAL NAME
0	O	PWRLED_L

Similar to Surprised Serial Hot Plug, each downstream port is correspondent to one equivalent 16-bit IO expander with the following Port/Address mapping table.

## 6.2 TIMING SEQUENCE FOR SURPRISED HOT PLUG OPERATION

Two timing charts are shown below to illustrate surprised hot insertion or removal under different scenarios. The first chart presents the timing relationship between system reset/reference\_clock and individual downstream reset/reference\_clock under initial power-up condition. The second chart demonstrates the timing sequence of clock and reset for device inserted or removed under power active condition.

## 7 CROSS-DOMAIN END-POINT

### 7.1 GENERAL DESCRIPTION

The PCIe Packet Switch supports Cross-Domain End-Point (CDEP) function. The function, when working in conjunction with the software running on the Main Host, enables data exchange among multiple PCIe-based hosts. This feature allows the system to implement fail-over or co-processor functionalities. These two use cases are briefly described in the following sections with the suitable CDEP Mode Switch Model for the use case.

#### 7.1.1 FAIL-OVER

In an error resilient system, a Remote/Back-up Host is set up to take over the Main Host in the event when Main Host has failed and the failure is detected. The CDEP Mode Switch Model facilitates the data exchange across domains of the Main and Remote/Back-up Hosts, and swaps the roles of the hosts in the event of the Main Host's failure. The CDEP Mode Switch Model used in the fail-over use case is shown in the illustration below.

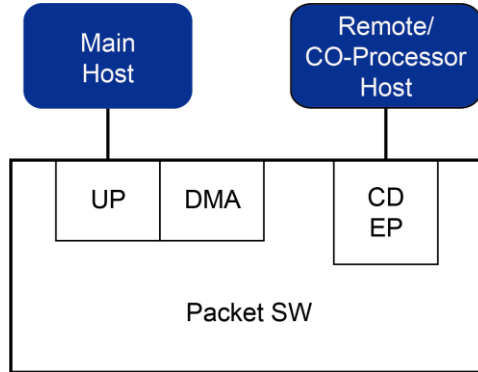

**Figure 7-1 Switch Reference Model Used in the Fail-Over Use Case**

In the event when the Main Host is unable to send regular messages to the Remote/Back-up Host, the Remote/Back-up Host can swap its role to the Main Host and its CDLEP port being a agent of upstream port to handle the traffic to/from downstream ports. The previous Main Host's upstream port will be reset during the link-down process initiated by the previous Main Host. The Switch has to ensure that the reset does not propagate to the entire upstream hierarchy in the previous Main Host's, so that the new Main Host can seamlessly manage the original End-Points. As a result, the impacts to the entire system are minimal during the fail-over transition.

#### 7.1.2 CO-PROCESSOR

The Remote Host/Co-processor can be connected to the CDLEP port to off-load the computation on the Main Host. The illustration below shows a Remote Host/Co-processor unit (CP), which works with the Main Host to form a two-processor system. The DMA function of the Main Host's upstream port is enabled to move data among the Main Host and Remote Host/Co-processor to accelerate intensive computation tasks.

**Figure 7-2 Switch Reference Model Used in the Co-Processor Use Case**

## 7.2 PORT CONFIGURATION

The Main Host can configure a Link CDEP port as a generic PCIe End-Point. This allows the Remote Host(s) the ability to link to the switch CDEP port during PCIe enumeration. The enumeration process includes BIOS start-up, operating system start-up, and/or subsequent PCIe hot-plug or dynamic enumerations initiated by the host operating system

Before the Main Host can enable the CDEP function, the Switch has to be configured into the CDEP mode and designate the CDEP port to as the upstream port of a generic end-point. The configuration is performed through EEPROM programming at power-up. In order to operate in the CDEP mode, the Switch is required to set Chip CD Mode for all of the tiles and Tile CD Mode per tile to select one of the CDEP port configurations. The Chip CD Mode and Tile CD Mode are defined in the [Device Configuration 0](#) and [2](#) Registers respectively.

The Switch is constructed of two tiles, one of which is a master tile and the other one is a slave tile. The upstream port is located in the master tile. In order to support the CDEP mode, the master tile has to contain a Cross-Domain Virtual End-Point (CDVEP). The CDVEP acts as an agent to bridge the Main Host and other host domain, and only exists in the master tile.

In addition to the CDVEP, the Switch has another type of End-Point, called Cross-Domain Line End-Point (CDLEP). The CDLEP is visible to the Remote Host (RH), but not the Main Host. The CDLEP bridges the communications between the Remote Host and other HOST. The table below describes the CDEP port's configurations by the tile types.

**Table 7-1 CDEP mode configuration**

Tile CD Mode	Master Tile	CDEP Configuration
0x	Y/N	Both CDEPs disabled
10	Yes	CDVEP enabled, but CDLEP disabled
11	Yes	CDVEP enabled, and CDLEP enabled
10	No	CDVEP disabled, but 1 CDLEP enabled
11	No	2 CDLEP enabled

In the master tile, only P4 can be designated as a CDLEP port. In slave tile, however, both of P0 and P4 can be selected as CDLEP ports<sup>2</sup>. Once the ports are chosen as CDLEP ports, the port numbers defined in Link Capability Register and MMIO Register offsets will be changed accordingly.

<sup>2</sup> When Tile CD mode is “10”, P0 is defined as a CDLEP port.

When Tile CD mode is “11”, both of P0 and P4 are defined as CDLEP ports.

## 7.3 BAR TRANSLATION FOR REMOTE HOST DOMAIN

The Remote Host configures a set of CDEP Link address translations to the Switch. The translations allow the Remote Host to access the CDEP Link's 64-bit BAR2/BAR3 and BAR4/BAR5 similar to accessing the other HOST locations. The Main Host software is responsible for managing the memory regions appropriately to implement and emulate the CDLEP end-point behaviors.

The Main Host defines either or both of a Direct Address Translation (DAT) range, and an Address Look-up Table (ALUT) for the BAR translations for the Remote Host to access to other HOST memory locations. The Main Host configures these settings prior to enabling the CDLEP port. After the Main Host programs the CDLEP port's BARs, the Remote Host is able to read/write to the Main Host or other Remote Host memory locations.

### 7.3.1 DIRECT ADDRESS TRANSLATION (DAT)

The Main Host arranges a contiguous memory block in the Remote Host domain by setting BAR Configuration registers with the chosen DAT. The BAR2/BAR3 and BAR4/BAR5 have their own corresponding contiguous memory blocks. These memory blocks are characterized by the Base bits and Window Size bits. If the upper address of incoming TLP matches with the Base bits, the upper address will be replaced with the translated address stored in Base Translation Registers ([BTR2/BTR3](#) and [BTR4/BTR5](#)). The lower address bits are defined by the Window Size bits and remain intact. They are considered to be an offset address from the base address. The Window Size is determined by the BAR configuration, and the minimum size is 1MB.

### 7.3.2 ADDRESS LOOK-UP TRANSLATION (ALUT)

In addition to the Direct Address Translation, the BAR2/BAR3 provides an alternative address translation mechanism, Address Look-Up Translation (ALUT). The ALUT allows multiple translated address blocks in a non-contiguous address range. The Window Size bits defined earlier can be partitioned into 7 index bits and the rest lower address bits can form Page Size bits. The minimum page size is 8KB (1MB divided by 128). The 7 index bits are used to access 128 entries. Each entry represents a translated address block and the host domain destination it is associated with.

The ALUT Access Control Registers at offset from [918h](#) to [920h](#) in the CDLEP is used to store 128 entries. When performing ALUT entry write, the software has to program the ALUT data into the CDLEP at offset [91Ch](#) and [920h](#) if the translated address is 64-bit. The software then updates the index and Command (set to write) fields of the CDLEP at offset 918h. When performing LUT entry read, the software has to program index and Command (set to read) fields of the CDLEP at offset 918h, and then read 91Ch and 920h to get the LUT data.

### 7.3.3 ID TRANSLATION

In the event when a PCIe read or write is initiated in the Remote Host PCIe domain, and the read/write targets the Main Host memory or an end-point in the Main Host PCIe domain, the PCIe Requestor ID field in the TLP header that targets the Main Host must be *translated* into the PCIe Requestor ID of the CDVEP. This is to ensure that the IOMMU access permissions granted by the Main Host operating system, virtual machine, and/or end-point driver, apply to these translated TLPs. If the target is to another Remote Host PCIe domain, the PCIe Requestor ID has to be translated into the PCIe Requestor ID of the destination CDLEP to ensure that a legal ID is used by the destination Remote Host system.

The domain id for Main Host is 0.

The domain id for Remote Host which is connected to T0P4/CDLEP port is 1.

The domain id for Remote Host which is connected to T1P0/CDLEP port is 2.

The domain id for Remote Host which is connected to T1P4/CDLEP port is 3.

## 7.4 BAR TRANSLATION FOR MAIN HOST DOMAIN

The Main Host also configures a set of CDEP Virtual address translations. The address translations allow accesses to a defined address range to be translated to the Remote Host memory addresses.

Similar to BAR Translation on the Remote Host domain described previously, the BAR Translation on the Main Host domain also supports two different approaches: the Direct Address Translation and the Address Look-Up table Translation. Please refer to the section of [CDVEP Configuration Registers](#) for related BAR translation setup registers such as [BAR Configuration](#), [BTR](#), [ALUT Access Control](#), and more.

The RID translation in Main Host domain is the same as the translation in the Remote Host domain. The only difference is in building the RID LUT. However, the [RID Table](#) is programmed by the Main Host in the default setting, not by hardware automatically.

## 7.5 SCRATCHPADS AND DOORBELLS

The CDEP Link and virtual interfaces may provide a set of switch-specific scratchpad and doorbell registers for uses in Remote Host-to-Main Host/Host communication. By definition, custom driver or diagnostic code is required to run on the hosts. As a result, the Main Host or Remote Host must determine their visibility when a CDEP port emulates a generic End-Point. The registers must appear in PCIe configuration space in user-defined regions.

If the Main Host intends to make the scratchpad and doorbell registers visible to the host, the Main Host should define a CDEP Link property that enables a non-prefetchable 32-bit BAR0 containing these scratchpad and doorbell registers. A 4K range is allocated for CDLEP within the BAR0 at an offset address defined in the table in section 9.2.3.

In each CDLEP or CDVEP, there are 8 sets of 32-bit scratchpad registers (CDLEP at offset [9E4h~A00h](#), and CDVEP at offset [9E4h~A00h](#)), and one set of 32-bit doorbell registers (CDLEP offset [9C4h~9D0h](#) and CDVEP offset [9C4h~9D0h](#)). The scratchpad registers are used to store information for communication among Remote Hosts and Main Host. The doorbell registers are utilized to process (set/clear/mask/unmask) interrupt in order to notify the destination host to fetch the data stored in scratchpad registers of the source host. The scratchpad registers can only be written by the host in same domain while doorbell registers can be set/clear by both of hosts either in the same domain or in different domain. If the Main Host uses the PCIe configuration command to access scratchpad and doorbell registers, it keep track of its End-Point-defined region and restrict its range so it does not go over the offset 9C4h. If the memory commands are used to access these registers in the CDLEP, the Main Host has to enable a non-prefetchable 32-bit BAR3. A 4K range is allocated for CDLEP within the BAR0/1 at an offset address defined in the address table of Device Specific Memory Mapped Configuration Mechanism.

## 8 DIRECT MEMORY ACCESS

### 8.1 GENERAL DESCRIPTION

The Switch provides DMA engines, two of which are available per switch tile. These are hardware blocks that includes a set of buffers to asynchronously read and write to I/O memory through the Switch's ports. Each DMA engine is configured through a corresponding PCIe Function, managed by a software device driver running on a connected Remote Host (RH) or Main Host (MH). The DMA engine is divided into single or multiple physical channels (2 per engine), providing a reserved portion of the buffer pool, and access to a set of virtual channels (2 per physical channel). The virtual channels allow the software initiator to submit lock-free requests, or partition access to the channel among a set of cooperating software subsystems. The initiator accesses the DMA engine using a physical/virtual channel (hereafter abbreviated as channel) to submit descriptors. Each descriptor tells the engine to read from a DMA source into one of the channel's internal buffers, and then performs a corresponding write to a DMA destination.

The Switch's DMA engines can be configured in a variety of ways, including:

- **Device Status Collection:** A host CPU can off-load blocking MMIO reads of device status registers to the DMA engine for asynchronous processing.
- **Peer-to-Peer EP Transfer:** A host CPU can off-load memory copies between a set of managed devices in the Switch.
- **Peer-to-Peer Remote Host Transfer:** A set of cooperating Remote Hosts connected through a pair of [CDEP](#) ports can use the DMA Engine as a RH-to-RH memory transport, implementing a message queue.

In this section, any description of register layouts and data formats uses little-endian ordering.

### 8.2 DMA CONFIGURATION

The Switch's EEPROM or a micro-controller connected via I2C interface first configures the Switch's DMA engines (functions), enabling the DMA functions to appear underneath appropriate ports. Then, the software attaches a DMA driver to the DMA function based on the software model for the switch deployment to initialize and manage the set of channels (descriptor queues), start/stop/restart the channels, and perform appropriate error handling.

#### 8.2.1 DMA FUNCTIONS

The Switch's EEPROM and switch configuration registers are set to indicate the ports under which the DMA functions will be visible to the connected RH or MH. This may include upstream ports, CDEP Link Ports, or virtual upstream ports.

The [Device Configuration 2 Register \(Offset 50Ch\)](#) defined in upstream port (Port 0) of a master tile or tile-based management port (Port 0) in slaves tiles is used to configure DMA function (bit[19:18]) under various CD modes (bit[17:16]) (Please refer to [CDEP Chapter](#) for CD mode definition). The DMA mode definition is represented by the following table.

**Table 8-1 DMA Mode definition**

DMA Mode	Master Tile	DMA Configuration
0x	Y/N	DMA functions disabled
10	YES	DMA functions enabled for P0 or P4 based upon CD mode
11	YES	DMA functions enabled for P0 only
10	NO	DMA functions enabled for P0 or P4 based upon CD mode
11	NO	DMA functions enabled for VUP only

Note: VUP stands for Virtual upstream port in slave tile.

### 8.2.1.1 DMA MODE BIT DEFINITION

- bit[1]: Decides if DMA function is enabled in the port connected to RH or MH.  
0: DMA function is disabled  
1: DMA function is enabled
- bit[0]: Determines if DMA function only visible to the MH's domain  
0: DMA function is visible to its own remote host or the MH's domain  
1: DMA function is only visible to the MH's domain

### 8.2.1.2 DMA MODE AND CD MODE

DMA function is defined in the various ports under different CD and DMA mode settings. These ports are respectively “P0 port in master tile”, “CDLEP port” and “Virtual Upstream Port in slave tiles”. A comprehensive table as shown below illustrates how the DMA functions (F1 or F2) being assigned to these three types of ports in terms of master/slave tile, CD and DMA modes.

### 8.2.1.3 ENUMERATION

The PCIe configuration space for each port that has been configured for DMA will enumerate one or more DMA Functions (Type0 configuration space headers), with a well-defined vendor, device, and class code indicating DMA, and a set of control registers associated with a non-prefetchable BAR. Software will enumerate each DMA Function and program BARs. These configuration registers for [function #1 or function #2](#) is defined in the chapter 9 of this document.

## 8.2.2 DMA CONTROL REGISTER

DMA engine (i.e. function) provides [a set of interface registers](#) for software to control the operation and monitor the status of DMA transfer for all channels managed by this function. These registers are accessed by mmio via a base address defined in non-prefetchable BAR0 and BAR1 registers associated with the channel and individual register offset defined in the section 5 of this document. For each channel, it will add an additional 100h offset to indicate the interface registers of one channel located in a 256-byte block. Hence, the access to one particular interface register in one of channels requires to set the address offset as follows: register offset + (number of channel) x 100h. Software can check the Channel ID field (bit[31:28]) of DMA Control and Status Register 0 at offset 00h to see if it is accessing the desired channel.

### 8.2.2.1 DMA DESCRIPTOR REGISTER

The DMA control register space will include a 64-bit pointer to the i/o address base of each channel's descriptor ring, and the size of the descriptor ring. Software will program the DMA registers to configure each descriptor ring, from which a channel will prefetch. The channel will support a total size for each descriptor ring of at most 4096 entries.

#### 8.2.2.1.1 DESCRIPTOR POINTER REGISTER

The I/O address base of each channel's descriptor ring is pointed by a [64-bit channel descriptor ring base pointer at register offset 0Ch and 10h](#). The software has to program these registers, so the hardware can prefetch the descriptors starting from there.

#### 8.2.2.1.2 DESCRIPTOR SIZE REGISTER

The size of descriptor ring can be programmed in [register offset 24h](#) (bit[12:0] in Channel Descriptor Ring Size for Prefetch register). The maximum descriptor ring size is 4096 entries. The bit[28:16] of this register indicates the next descriptor index is going to be prefetched.

### 8.2.2.2 DMA OPERATIONAL REGISTER

The DMA control register space will include a control register ([DMA Control and Status Register 1](#) at register offset 20h) for each channel to start, stop, abort, pause, and resume DMA activity for the channel. Software will update the control register to start the engine once it is ready to begin submitting requests. Software will update the control register if it needs to pause, stop, or otherwise reconfigure a channel.

After starting the DMA activity for that virtual channel (i.e. write "1" to bit[0] of DMA Control and Status Register 1), the software can update the control register any time by commanding the DMA engine to pause, abort or stop operation. Following is a summary for these three operations.

#### 8.2.2.2.1 PAUSE (bit[1])

When set, the DMA activity is paused to the next active descriptor after completing the processing on current descriptor. Then, the DMA Pause Done status (bit[16]) is turned on to represent the DMA is in “paused” condition. If DMA Pause Interrupt Enable (bit[3]) is set, an interrupt will be issued to notify the software when bit[16] is set. For pause operation, there is no any descriptor or data being dropped and the DMA operation can be resumed any time by clearing the Pause Control (bit[1]).

#### 8.2.2.2.2 ABORT (bit[2])

When set, the DMA activity drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data. The pointer will move to the next active descriptor. Then, the DMA Abort Done status (bit[17]) is turned on to represent the DMA is in “aborted” condition. If DMA Abort Interrupt Enable (Bit 6) is set, an interrupt will be issued to notify the software when bit[17] is set. In abort condition, the DMA operation can be resumed any time by clearing the Abort Control (bit[2]) and setting DMA Start (bit[0]). Then, DMA begins to process the next active descriptor. In fact, the software is also allowed to reprogram interface registers for re-initialization and start from the base descriptor pointer.

#### 8.2.2.2.3 STOP (bit[7])

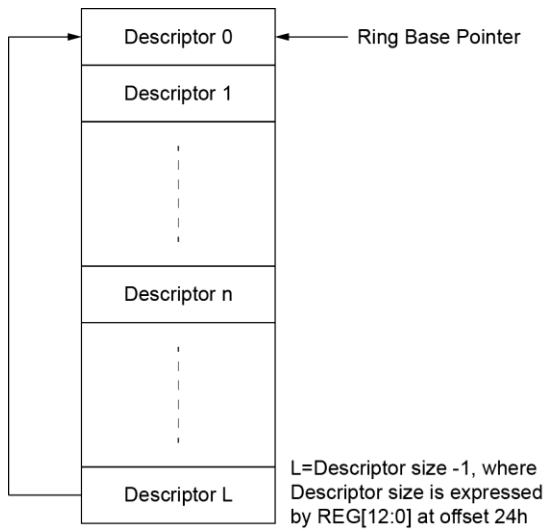

When set, the DMA activity drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data. The channel interface registers are all cleaned to default state except Interrupt flag bit if DMA stop enable is set earlier. Then, the DMA Stop Done status (bit[18]) is turned on to represent the DMA is in “stopped” condition. If DMA Stop Interrupt Enable (bit[5]) is set, an interrupt will be issued to notify the software when bit[18] is set. In stop condition, the data buffer contents pointed by the previous processed descriptor will be dropped as well, so the software needs to reprogram interface registers for re-initialization before resuming DMA activity by setting DMA Start (bit[0]).

### 8.3 DMA DESCRIPTORS AND TRANSFERS

Each DMA channel will initiate descriptor pre-fetch when the channel is enabled and its ownership register is updated, indicating the valid range of descriptors to prefetch. When a valid descriptor is found, a DMA transfer will be scheduled with the underlying DMA engine in a fair manner with respect to other descriptors from other channels. The descriptor will be re-written by the DMA engine when the DMA transfer is complete, or if the DMA transfer fails due to an error. The switch will also update the ownership register to indicate the range of completed descriptors. Software will then examine the completed descriptors and take appropriate action.

#### 8.3.1 DESCRIPTORS

Descriptors are located in the system memory. All of descriptors in a ring have to be concatenated together without gap (see figure 1. below). The switch will calculate the address offset automatically by adding the index of descriptor multiplied with the byte count of a single-descriptor to the ring base descriptor pointer for prefetch.

**Figure 8-1 DMA Descriptor Map**

### 8.3.1.1 INITIALIZATION

Software will initialize a valid descriptor by writing it to memory at the next free location in a channel's descriptor ring. Software will ensure that the descriptor's valid bit is written only after all other descriptor fields have been initialized. Software will update the ownership register to schedule execution of all initialized descriptors with the DMA engine.

### 8.3.1.2 OWNERSHIP

After all descriptor fields have been initialized, Software will update the ownership registers located at the register offset 04h and 08h by setting valid status. The [descriptor ownership 0 register](#) (04h) represents the first 32 descriptors' valid status starting from bit[0] while the [descriptor ownership 1 register](#) (08h) stands for the next 32 descriptors' valid status. The switch will pre-fetch the descriptors with valid status turned on continuously until the descriptor with valid status being cleared. After the descriptors have been processed, the switch will update the ownership registers by clearing valid status in the order it was received.

### 8.3.1.3 PRE-FETCH

Software needs to update the Channel Descriptor Ring Size for [Pre-fetch register at offset 24h](#) by writing total descriptor numbers into bit[12:0]. Starting from the 1st descriptor pointed by ring base pointer register (0Ch and 10h), the descriptors will be pre-fetched by the switch continuously. The Channel Descriptor Current Pointer register at offset 14h indicates which descriptor is under processing. The switch will also take a residual function over the descriptor numbers divided by 64. If the remainder is less than or equal to 64, the switch will go back to prefetch the 1st descriptor after hitting the last descriptor.

When Software prepares to update the ownership registers during the DMA operation, it requires to check Descriptor current pointer (14h) viewed by the switch in order to update the correct 64-bit sliding window, which is advanced in terms of descriptor units.

## 8.3.2 TRANSFER

Software will define in the descriptor a 64-bit i/o source address, 64-bit i/o destination address, and transfer length up to 8MB. Switch will divide the DMA transfer into appropriate pairs of Memory Read and Write TLPs based on the current switch settings for Max\_Payload\_Size and Max\_Read\_Request\_Size, along with any 4k boundaries crossed by the range of addresses. Other than 64-bit i/o source and 64-bit i/o destination address, Software will also define 4-bit source domain and

4-bit destination domain in the descriptor for moving data across domains. Switch needs to generate Read or Write TLPs with a translated RID if the TLP destined domain is different from the domain where the DMA function is located.

### 8.3.2.1 LOCAL DOMAIN TRANSFER

For a local DMA transfer (i.e. no crossing host domains, the SDV and DDV must be “0” in the CTRL word of descriptors), the switch will refer to [Max Payload Size](#) and [Max Read Request Size](#) defined in PCIe configuration space in where the DMA function is resided for generating MRD and MWR TPLs along with any 4k boundaries crossed by the range of addresses.

### 8.3.2.2 CROSS DOMAIN TRANSFER

As to a cross-host-domain DMA transfer (i.e. either SDV or DDV or both are “0”), the switch will refer to Max\_Payload\_Size and Max\_Read\_Request\_Size of other host domains defined in register offset [28h, 2Ch and 30h](#), which are usually programmed by Main Host. The switch will check the domain id carried in descriptor to choose the appropriate Max\_Payload\_Size and Max\_Read\_Request\_Size for creating MRD and MWR TLPs. Please note that the Main Host software has to program the correct values of Max\_Payload\_Size and Max\_Read\_Request\_Size for each domain by following the definition in PCIe configuration device control registers of that domain. Otherwise, it will cause undesired result in packet transfers.

As the DMA transfer source domain is different from destination domain, the Requester ID needs to be translated into a legal BDF ID of the destination domain. The software is required to program the captured bus number of CDV or CDL into domain bus number defined in register offset [34h, 38h and 3Ch](#). Regarding the captured bus number, the software can refer to CDEP data 0 register at offset A04h of CD port. The switch will check the domain id carried in descriptor to choose the appropriate bus number for creating RID of MRD and MWR TLPs.

### 8.3.3 DESCRIPTOR LAYOUT

The descriptor is formed by an 8-DW data block. The Figure 2 (see below) presents the layout of these DWs containing control word, source domain/address, destination domain/address, transfer byte count and others.

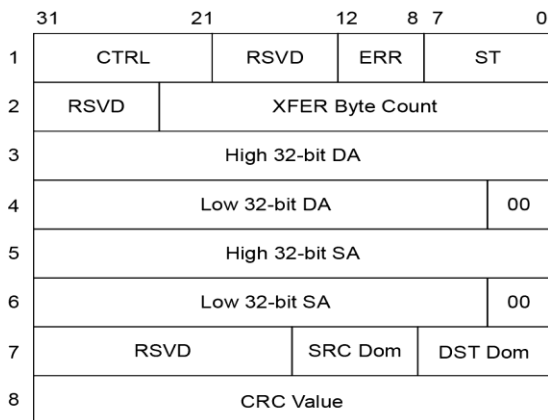

Figure 8-2 DMA Descriptor Layout in an 8-DW block

#### 8.3.3.1 DOMAIN AND ADDRESS FIELD

The 64-bit I/O destination address and source address are located from the 3rd DW to 6th DW. They must be D-Word aligned. Also in the 7th DW, it defines the destination domain id (bit[7:0]) and source domain id (bit[15:8]) used for cross-domain DMA operation. Each domain id is expressed by LSB 4-bit that represents for 4 different host domain (0 ~ 3) supported by one packet switch. As to MSB 4-bit, they are reserved for future use.

### 8.3.3.2 TRANSFER COUNT FIELD

The bit[22:0] in the 2nd DW stands for the transfer byte count for one descriptor can be up to 8MB.

### 8.3.3.3 CONTROL FILED

There are several bits defined in CTRL field of 1st DW for further formatting and enabling the source and destination locations. Please see Table 3 for illustrating bit definition in CTRL filed.

**Table 8-3 Bit Definition in CTRL field of the 1<sup>st</sup> DW**

Bit	Name	Description
31	EOT	End of transfer
30	INT	Issue interrupt when DMA done
29	TPH	TPH function enable
28	NOP	No operation
27	FLH	Dlush any cached data
26	SAV	Source address is valid
25	DAV	Destination address is valid
24	64bit	Rnable 64 bit address
23	SAV	Source domain is valid
22	DDV	Destination domain is valid
21	CRC	Enable CRC checksum

- ◇ EOT(End of Transfer): Defined in bit[31]. When set, it indicates the current DMA transfer is completed. The interpretation on EOT is various for different DMA modes. If the EOT valid bit defined in the DMA control register 0 is set, the switch will update the EOT bit in descriptor from 0 to 1 after transfer count indicated in descriptor is ended.
- ◇ 64bit: Defined in bit[24]. When set, the I/O address is in 64-bit physical memory. Otherwise, it is in 32-bit physical memory.
- ◇ SAV: Defined in bit[26]. When set, it means the I/O source address is valid. If cleared, the I/O source address is not valid, which is the condition that only destination DMA channel is enabled for executing host to host DMA.
- ◇ DAV: Defined in bit[25]. When set, it means the I/O destination address is valid. If cleared, the I/O destination address is not valid, which is the condition that only source DMA channel is enabled for executing host to host DMA.
- ◇ SDV: Defined in bit[23]. When set, it means the source domain id is valid and MRD will be issued to that domain by following its max payload size and read request size. It implies that DMA source and DMA function (or descriptors) are located in different domains. If cleared, it might be in the condition of either only DMA destination is positioned in a different domain from DMA function or just for a local (i.e. same domain) DMA transfer between source and destination.
- ◇ DDV: Defined in bit[22]. When set, it means the destination domain id is valid and MWR will be issued to that domain by following its max payload size. It implies that DMA destination and DMA function (or descriptors) are located in different domains. If cleared, it might be in the condition of either only DMA source is positioned in a different domain from DMA function or just for a local (i.e. same domain) DMA transfer between source and destination.
- ◇ NOP: Defined in bit[28]. Software can configure a no-op (zero length) descriptor by setting NOP of CTRL field. Once this bit is turned on, that performs no Reads or Writes. and
- ◇ FLH: Defined in bit[27]. Software can configure a cache flush descriptor by setting FLH of CTRL field. A cache flush descriptor, that forces the DMA engine to flush its buffer cache, and cancel any outstanding DMA Reads (thereby avoiding lengthy Completion Timeout conditions). Once this bit is turned on, the DMA activity drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data. The channel interface registers are all cleaned to default state as well. Software can check if DMA Start (bit[0] of register at offset 20h) is cleared to ensure “flush” event has completed. This “flush” feature provides a way for Software to restart DMA operation in terms of reinitializing the DMA ring buffer and interface registers.
- ◇ INT: Defined in bit[30]. Software may configure a descriptor with a flag (setting INT of CTRL field) to interrupt the software device driver on the completion (or failure) of the corresponding descriptor, using an interrupt mechanism defined by the containing DMA Function’s configuration registers. Software needs to clear the interrupt status by writing “1” to the bit[31] (Interrupt Flag) of register at offset 20h.
- ◇ In DMA Engine (Function) Configuration registers for function 1 or 2, it defines various interrupt mechanisms such as INTx Interrupt message enabled by bit[10] of command register at offset 04h (via configuration space), MSI/Multiple

MSI enabled by bit[16]/bit[22:20] of MSI control register at offset 48h or MSI-X enabled by bit[31] of MSI-X control register at offset B0h.

- ◇ TPH: Defined in bit[29]. Software may configure a descriptor with a flag (setting TPH of CTRL field) to indicate that the posted memory writes issued by the DMA engine for this descriptor should include a set of TLP Processing Hints (TPH). The TPH will consist of setting the TH bit in each posted write's TLP header, and incorporating an 8-bit ST (7:0) steering tag data field that is found in the DMA descriptor. The steering tag in the TLP header is copied from ST value defined in bit[7:0] of 1st DW in descriptor.

#### 8.3.3.4 ERR FIELD

This 5-bit field can encode into 32 errors at most. In descriptor level, the DMA might detect the following errors such as Data Poison (encoded as 12, which is corresponding to bit[12] in AER), Completion Time-Out (bit[14]), Completer Abort (bit[15]), ECRC error (bit[19]) and Unsupported Request (bit[20]). If there are more than two errors (included) happening at the same time, it always reports the error defined with the least bit.

#### 8.3.3.5 ST FIELD

It represents 8-bit steering tag. This 8-bit data is valid only when TPH bit set in control field.

#### 8.3.3.6 CRC FIELD

Software may configure a descriptor with a flag to indicate that the DMA engine should compute a CRC-32 checksum of the data bytes (not including headers) that were read as part of the DMA transfer. The calculated CRC-32 will be written back to the descriptor on completion.

By setting CRC of CTRL field (bit[21] of the 1st DW), it enables DMA engine to compute a CRC-32 checksum over the raw data bytes of buffer pointed by the descriptor. It uses PCIe ECRC-32 polynomial and calculation is in a DW alignment. Upon the completion of descriptor processing, the final CRC-32 checksum result will be written back to the 8th DW of descriptor.

## 8.4 ERROR REPORTING AND HANDLING

The software managing a DMA function and associated channels must be able to define appropriate error handling behaviors for the DMA processing, including the handling of DMA memory read failures. To implement appropriate error handling for DMA:

### 8.4.1 ERROR REPORTING

Software will discover the Advanced Error Reporting (AER) capability in the configuration space of each DMA Function. Software will then enable AER, and configure the AERUCES, AERUCEM, AERUCESEV, AERCS, AERCEM, AERCC, AERHL, and AERTLP registers appropriately. The switch will update these registers and issue M\_ERR messages as the DMA engine detects errors when processing a descriptor from the corresponding function. The switch will also rewrite the descriptor affected by an error with an error status field, indicating the corresponding PCIe error that caused the DMA to fail (e.g. DP, ECRC, CTO).

#### 8.4.1.1 REPORTING VIA FUNCTION

In DMA Engine (Function) Configuration registers for function 1 or 2, it defines Advanced Error Reporting (AER) capability at byte offset 100h that followed by AERUCES, AERUCEM, AERUCESEV, AERCES, AERCEM, AERCC and AERHL registers from a byte offset 104h to 128h.

#### 8.4.1.2 REPORTING VIA CHANNEL

When processing any descriptor in all of channels assigned to that DMA function, it will issue UCE\_MSG if any of UCE is detected and also the corresponding UCE bit in AERUCEM is cleared. Meanwhile, the AERUCES would be copied to

Channel UCES register defined in DMA interface register at offset 44h, so it will know which channel causing UCE. Furthermore, bit[25:24] of Channel UCES register will also indicate what type of DMA transaction running into Uncorrectable error. bit[24] represents the detected error happening in fetching descriptor while bit[25] shows that error detected in reading data into DMA buffer. The DMA engine will issue interrupt if UCE Interrupt Enable bit (bit[17] of DMA Control and Status 0) is turned on.

#### 8.4.1.3 REPORTING VIA DESCRIPTOR

To continuously trace down from where the UCE is coming, the DMA engine will also write back the error status to the descriptor which is affected by an error with a 5-bit error status field (bit[12:7] of 1st DW in descriptor). A 5-bit error status field can represent any of the PCIe UEs defined in AERUCES (e.g. error field=12 in descriptor would mean DP because DP is the 12th bit of AERUCES). Once Multiple UEs happen simultaneously, the lowest bit position in AERUCES will be recorded. (e.g. if DP (bit[12] in AERUCES) and Malformed TLP (bit[18] in AERUCES) are detected, only the DP reported as error since it is a lowest bit)

### 8.4.2 ERROR LOGGING

The DMA Function will provide a default (or configurable) value for AERCAP + 18h AERCC.MHRC, and errors will be logged appropriately into AERHL and AERTLP as detected when processing a descriptor from the corresponding function. The default value for AERCC.MHRC is zero, so there is only one TLP header with error(s) will be logged into AERHL.

### 8.4.3 DATA INTEGRITY

The switch will implement ECRC checking and ECRC generation for TLPs passing through the DMA engine. As such, the DMA Function will set AERCC.ECC=1 and AEREGC=1 in the AER capability, DMA Reads will verify ECRC, and DMA Writes will generate ECRC.

In AERCC register of DMA function configuration space, it defines ECC (bit[7]) and EGC (bit[5]) as “1” so the system software can set ECE = 1 (bit[8]) and EGE = 1 (bit[6]) to enable the switch to perform ECRC checking and ECRC generation for TLPs passing through the DMA engine.

### 8.4.4 ERROR HANDLING FOR UNCORRECTABLE ERROR DETECTED

The switch will provide software the channel status to determine whether a particular detected error will automatically stop the channel, or simply mark the descriptor as being in error, and continue processing the next descriptor. Once detecting uncorrectable error, the DMA will write back error status into the descriptor which is affected by error(s). Also, the switch will take the following steps for two scenarios.

#### 8.4.4.1 ERROR IN DATA BUFFER

If the error occurs in the TLPs that are CPLDs for storing into DMA data buffer, the DMA activity drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data. The pointer will move to the next active descriptor and this would be treated like an H/W abort event. This channel is aborted and it is up to Software to restart DMA from the next descriptor or re-program the DMA control register to start from the base descriptor.

#### 8.4.4.2 ERROR IN DESCRIPTOR

If the error occurs in the TLPs that are CPLDs for storing into Prefetch descriptor cache, the DMA activity not only drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data, but also dumps the following descriptors since they are damaged as well. So this channel is stopped and requires Software to reprogram interface registers for re-initialization before resuming DMA activity by setting DMA Start (bit[0]).

## 8.4.5 ERROR HANDLING FOR DMA READ

The switch will provide a register for the DMA function that software can use to determine whether an error on DMA Memory Read will cause the function and/or descriptor to report an error immediately (without writing), or will cause the function and/or descriptor to report an error only after writing to the DMA destination address a Poisoned (DP) Memory Write TLP for each corresponding Memory Read that failed.

If the UCE occurring in DMA read for CPLDs acquired from source address, the error report scheme (bit[18] in DMA Control and Status Register 0) can be configured in two different modes.

- ◇ If bit[18] is set, DMA reports UCE event after writing DP TLP to destination address. The DP TLP is generated for each corresponding memory read that failed.
- ◇ If bit[18] is cleared, DMA reports UCE event immediately without writing DP TLP to destination address.

## 9 REGISTER DESCRIPTION

### 9.1 REGISTER TYPES

This chapter details the Packet Switch registers, including

- Bit names
- Description of register functions
- Type, refer to Table 9-1
- Whether the default value can be modified by EEPROM and/or I2C/SMBUS
- Default value

**Table 9-1 Register Types**

REGISTER TYPE	DEFINITION
RO	Read Only
RW	Read / Write
RWIC	Read / Write 1 to Clear
RWIO	Read/Write 1 Only
RsvdP	RO and must return 0 when read.

### 9.2 REGISTER ACCESS

Each Switch Port implements a 4-KB Configuration Space which includes the lower 256 bytes PCI-compatible Configuration Space, and the upper 3840 bytes PCI Express Extended Configuration Space. There are several mechanisms that can access the Configuration Space:

- PCI-compatible Configuration Mechanism
- PCI Express Enhanced Configuration Access Mechanism
- Device-specific Memory Mapped Configuration Mechanism
- I2C Slave Interface
- SMBUS Slave Interface

#### 9.2.1 PCI-COMPATIBLE CONFIGURATION MECHANISM

The PCI-compatible Configuration Mechanism provides standard access to the first 256 bytes of the PCI Express Configuration Space. The mechanism uses PCI Type 0 and Type 1 Configuration transactions to access the Packet Switch Configuration registers.

#### 9.2.2 PCI EXPRESS ENHANCED CONFIGURATION ACCESS MECHANISM

The PCI Express Enhanced Configuration Access Mechanism is implemented on all PCI Express PCs. It provides a memory-mapped address space in the root complex, through which the root complex translates a memory access into one or more configuration requests. Device drivers normally use an application programming interface (API) provided by the Operating System (OS) to use this mechanism. The mechanism can access all Packet Switch registers.

#### 9.2.3 DEVICE\_SPECIFIC MEMORY MAPPED CONFIGURATION MECHANISM

The Device-Specific memory-Mapped Configuration Mechanism provides a method to access the configuration registers of all ports in a single 512KB memory map. The registers of each port are contained within a 4-KB range.

To use this mechanism, BIOS/OS needs to set BAR 0 and BAR 1 registers of up port at boot time. After BAR 0 and BAR 1 are enumerated, Port 0 registers can be access with Memory Reads from and Writes to the first 4 KB, Port 1 registers can be accessed with Memory Reads from and Writes to the 2<sup>nd</sup> , and so forth.

### 9.3 TRANSPARENT MODE CONFIGURATION REGISTERS

When the port of the Switch is set to operate at the transparent mode, it is represented by a logical PCI-to-PCI Bridge that implements type 1 configuration space header. The following table details the allocation of the register fields of the PCI 2.3 compatible type 1 configuration space header.

Other than the PCI 2.3 compatible configuration space header, the Switch also implements PCI express extended configuration space header, which includes advanced error reporting, virtual channel, and power budgeting capability

registers. The following table details the allocation of the register fields of PCI express extended capability space header. The first extended capability always begins at offset 100h with a PCI Express Enhanced Capability header and the rest of capabilities are located at an offset greater than 0FFh relative to the beginning of PCI compatible configuration space.

## 9.4 CDLEP CONFIGURATION REGISTERS

When the port of the Switch is set to operate at the cross-domain end point mode, it is represented by an Other Bridge that implementstype 0configuration space header. The following table details the allocation of the register fields of the PCI 2.3 compatible type 0 configuration space header.

Please be aware of those registers marked as port 0 only, which are defined for management purpose.

Other than the PCI 2.3 compatible configuration space header, the Switch also implements PCI express extended configuration space header, which includes advanced error reporting, virtual channel, and power budgeting capability registers. The following table details the allocation of the register fields of PCI express extended capability space header. The first extended capability always begins at offset 100h with a PCI Express Enhanced Capability header and the rest of capabilities are located at an offset greater than 0FFh relative to the beginning of PCI compatible configuration space.

Other than the PCI 2.3 compatible configuration space header, the Switch also implements PCI express extended configuration space header, which includes advanced error reporting, virtual channel, and power budgeting capability registers. The following table details the allocation of the register fields of PCI express extended capability space header. The first extended capability always begins at offset 100h with a PCI Express Enhanced Capability header and the rest of capabilities are located at an offset greater than 0FFh relative to the beginning of PCI compatible configuration space.

These 16 32-bit registers construct a Requester ID (RID) look-up table storing the RID of TLP issued from Main Host, which connected to the upstream port directly. The table content can be either built by hardware automatically or written by software of management CPU. There are control signals defined in the 14<sup>th</sup> and 15<sup>th</sup> bits of [Device Configuration 2 Register at offset 50Ch of Port 0](#) to decide RID LUT build-up mechanism for CDVEP P0 and CDLEP P4 respectively.

## 9.7 DMA ENGINE INTERFACE REGISTERS

To enable DMA function, the packet switch defines a set of interface registers for software to control the DMA engine and monitor the status of DMA transfer. There are two DMA engines (DMA\_0 and DMA\_1) in this Switch to face either one common or two different CPU domains respectively, so it defines an independent interface for software to access its own registers in its own CPU domain. The interface registers contain per-channel DMA control and status registers, descriptor ownership registers, descriptor pointer registers and property registers (such as max payload size, max read request size and bus number of CDEP port etc.) for cross-domain DMA transfer.

The interface registers are mapped to multiple 256-byte register blocks in memory mode and each 256-byte register block represents one channel. The register blocks can be accessed by the DMA Memory Base Address, which is obtained by DMA Base Address Register 0 (Func1, CFG offset 10h or Func2, CFG offset 10h based upon different DMA mode selection, and please note that each DMA engine is viewed as a PCIe function by enumeration).

## 10 POWER SEQUENCE

As long as PERST# is asserted, all PCI Express functions are held in reset. The main supplies ramp up to their specified levels (0.95V/1.8V). Sometime during this stabilization time, the REFCLK starts and stabilizes. After elapsing some time (i.e. 100 us) for the power and clock to become stable, PERST# is deasserted high and the PCI Express functions can start up.

## 11 IEEE 1149.1 COMPATIBLE JTAG CONTROLLER

An IEEE 1149.1 compatible Test Access Port (TAP) controller and associated TAP pins are provided to support boundary scan in PI7C9X3G1224GP for board-level continuity test and diagnostics. The TAP pins assigned are TCK, TDI, TDO, TMS and TRST\_L. All digital input, output, input/output pins except TAP pins and SERDES pins are tested.

### 11.1 INSTRUCTION REGISTER

The IEEE 1149.1 Test Logic consists of a TAP controller, an instruction register, and a group of test data registers including Bypass and Boundary Scan registers. The TAP controller is a synchronous 16-state machine driven by the Test Clock (TCK) and the Test Mode Select (TMS) pins. An independent power on reset circuit is provided to ensure the machine is in TEST\_LOGIC\_RESET state at power-up.

PI7C9X3G1224GP implements a 5-bit Instruction register to control the operation of the JTAG logic. The defined instruction codes are shown in the following table. Those bit combinations that are not listed are equivalent to the BYPASS (1111) instruction.

**Table 11-1 Instruction Register Codes**

### 11.2 BYPASS REGISTER

The required bypass register (one-bit shift register) provides the shortest path between TDI and TDO when a bypass instruction is in effect. This allows rapid movement of test data to and from other components on the board. This path can be selected when no test operation is being performed on the PI7C9X1224GP.

### 11.3 DEVICE ID REGISTER

This register identifies Diodes as the manufacturer of the device and details the part number and revision number for the device.

**Table 11-2 JTAG Device ID Register**

Bit	Type	Value	Description
31-28	RO	0001	Version number
27-12	RO	0001011000010110	Last 4 digits (hex) of the die part number
11-1	RO	010001111111	Diodes identifier assigned by JEDEC
0	RO	1	Fixed bit equal to 1

## 11.4 BOUNDARY SCAN REGISTER

The boundary scan register has a set of serial shift-register cells. A chain of boundary scan cells is formed by connected the internal signal of the PI7C9X3G1224GP package pins. The VDD, VSS, and JTAG pins are not in the boundary scan chain. The input to the shift register is TDI and the output from the shift register is TDO. There are 4 different types of boundary scan cells, based on the function of each signal pin.

The boundary scan register cells are dedicated logic and do not have any system function. Data may be loaded into the boundary scan register master cells from the device input pins and output pin-drivers in parallel by the mandatory SAMPLE and EXTEST instructions. Parallel loading takes place on the rising edge of TCK.

## 12 ELECTRICAL AND TIMING SPECIFICATIONS

### 12.1 ABSOLUTE MAXIMUM RATINGS

**Table 12-1 Absolute Maximum Ratings**

(Above which the useful life may be impaired. For user guidelines, not tested.)

Item	Absolute Max. Rating
Storage Temperature	-65 °C to 150 °C
Junction Temperature, T <sub>j</sub>	125 °C
Digital core and analog supply voltage to ground potential (VDDC and AVDD)	VDDC +10%
Digital I/O and analog high supply voltage to ground potential (VDDR and AVDDH)	VDDR + 10%
DC input voltage for Digital I/O signals	2.75V
ESD Rating Human Body Model (JEDEC Class 2) Charge Device Model (JEDEC Class 3)	HBM 2KV CDM 500V

**Note:**

Stresses greater than those listed under MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect reliability.

- Peak to peak AC noise < 5% of DC level.
- Peak to peak AC noise < 3% of DC level.

### 12.3 PCIE REFERENCE CLOCK REQUIREMENTS

**Note:**

- SSC permits a +0, -5000ppm modulation of the clock frequency at a modulation rate not to exceed 33 kHz.
- Measurements at 5.0 GT/s require an oscilloscope with a bandwidth of  $\geq 12.5$  GHz, or equivalent, while measurements made at 2.5 GT/s require a scope with a least 6.2 GHz bandwidth. Measurement at 5.0 GT/s must deconvolve effects of compliance test board to yield an effective measurement at Tx pins. 2.5 GT/s may be measured within 200 mils of Tx device's pins, although deconvolution is recommended. For measurement setup details, refer PCI Express Base Specification Revision 3.1, Figure 4-32 to and Figure 4-33. At least  $10^6$  UI of data must be acquired.
- Transmitter jitter is measured by driving the Transmitter under test with a low jitter "ideal" clock and connecting the DUT to a reference load.
- Transmitter raw jitter data must be convolved with a filtering function that represents the worst case CDR tracking BW. 2.5 GT/s and 5.0 GT/s use different filter functions that are defined in PCI Express Base Specification Revision 3.1, Figure 4-49. After the convolution process has been applied, the center of the resulting eye must be determined and used as a reference point for obtaining eye voltage and margins.
- $V_{TX-AC-CM-PP}$  and  $V_{TX-AC-CM-P}$  are defined in PCI Express Base Specification Revision 3.1, Section 4.3.3.2. Measurement is made over at least  $10^6$  UI.
- The Tx PLL Bandwidth must lie between the min and max ranges given in the above table. PLL peaking must lie below the value listed above. Note: the PLL B/W extends from zero up to the value(s) specified in the above table.
- Measurements are made for both common mode and differential return loss. The DUT must be powered up and DC isolated, and its data+/data- output must be in the low-Z state at a static value.
- A single combination of PLL BW and peaking is specified for 2.5 GT/s implementations. For 5.0 GT/s, two combinations of PLL BW and peaking are specified to permit designers to make a tradeoff between the two parameters. If the PLL's min BW is  $\geq 8$  MHz, then up to 3.0 dB of peaking is permitted. If the PLL's min BW is relaxed to  $\geq 5.0$  MHz, then a tighter peaking value of 1.0 dB must be met. In both cases, the max PLL BW is 16 MHz.
- Reduced swing output, defined by  $V_{TX-DIFF-PP-LOW}$  must be implemented as shown in PCI Express Base Specification Revision 3.1, Figure 4-37 with no de-emphasis.
- For 5.0 GT/s, de-emphasis timing jitter must be removed. An additional HPF function must be applied as shown in PCI Express Base Specification Revision 3.1, Figure 4-49. This parameter is measured by accumulating a record length of  $10^6$  UI while the DUT outputs a compliance pattern.  $T_{MIN-PULSE}$  is defined to be nominally 1 UI wide and is bordered on both sides by pulses of the opposite polarity. Refer to PCI Express Base Specification Revision 3.1, Figure 4-38.
- Root Complex Tx de-emphasis is configured from Upstream controller. Downstream Tx de-emphasis is set via a command, issued at 2.5 GT/s. For detail, refer to the appropriate location in PCI Express Base Specification Revision 3.1, Section 4.2.
- Tx CM noise for 8.0 GT/s is measured at TP1 without de-embedding the breakout channel. The parameter captures device CM noise only and is not intended to capture system CM noise. For 5.0 GT/s an LPF with a -3 dB corner at 2.5 GHz is applied to the raw data. For 8.0 GT/s the filter's -3 dB corner is at 4.0 GHz.
- $I_{TX-SHORT}$  and  $V_{TX-DC-CM}$  stipulate the maximum current/voltage levels that a transmitter can generate and therefore define the worst case transients that a receiver must tolerate.
- All platforms that have transmitters supporting 8.0 GT/s must implement the 176-265 nF  $C_{TX}$  value. Platforms operating at 2.5 or 5.0 GT/s only may implement over a range of 75 to 265 nF.

$V_{TX-BOOST-RS}$	Tx boost ratio for reduced swing	2.5 (min)	dB	Assumes $\pm 1.0$ dB tolerance from diagonal elements in PCI Express Base Specification Revision 3.1, Figure 4-45.
$EQ_{TX-COEFF-RES}$	Tx coefficient resolution	1/24 (max) 1/63 (min)	N/A	

Note:

- Voltage measurements for  $V_{TX-FS-NO-EQ}$  and  $V_{TX-RS-NO-EQ}$  are made using the 64-zeroes/64-ones pattern in the compliance pattern.
- Voltage limits comprehend both full swing and reduced swing modes. The Tx must reject any changes that would violate this specification. The maximum level is covered in the  $V_{TX-FS-NO-EQ}$  measurement which represents the maximum peak voltage the Tx can drive. The  $V_{TX-EIEOS-FS}$  and  $V_{TX-EIEOS-RS}$  voltage limits are imposed to guarantee the EIEOS threshold of 175 mVPP at the Rx pin. This parameter is measured using the actual EIEOS pattern that is part of the compliance pattern and then removing the ISI contribution of the breakout channel. The transmitter must advertise a value for LF during TS1 at 8.0 GT/s that ensures that these parameters are met.
- PWJ parameters shall be measured after DDJ separation.
- Measured with optimized preset value after de-embedding to Tx pin.
- The 18 ps number takes into account measurement error.
- The -3.0 dB number takes into account measurement error. For some Tx package/driver combinations  $ps21_{TX}$  may be greater than 0 dB.

- Receiver eye margins are defined into a 2x 50  $\Omega$  reference load.
- The four inherent timing error parameters are defined for the convenience of Rx designers, and they are measured during Receiver tolerancing.
- Two combinations of PLL BW and peaking are specified at  $\geq 5.0$  GT/s to permit designers to make tradeoffs between the two parameters. If the PLL's min BW is  $\geq 8$  MHz, then up to 3.0 dB of peaking is permitted. If the PLL's min BW is relaxed to  $\geq 5.0$  MHz, then a tighter peaking value of 1.0 dB must be met. Note: a PLL BW extends from zero up to value(s) defined as the min or max in the above table. For 2.5 GT/s a single PLL bandwidth and peaking value of 1.5-22 Mhz and 3.0 dB are defined.
- Measurements must be made for both common mode and differential return loss. In both cases the DUT must be powered up and DC isolated, and its D+/D- inputs must be in the low-Z state.
- The Rx DC single ended impedance must be present when the Receiver terminations are first enabled to ensure that the Receiver Detect occurs properly. Compensation of this impedance can start immediately and the Rx Common Mode Impedance (Constrained by  $R_{L-RX-CM}$  to 50  $\Omega \pm 20\%$ ) must be within the specified range by the time Detect is entered.
- Common mode peak voltage is defined by the expression:  $\max\{|(V_{D+}-V_{D-}) - V_{CMDC}\}$ .
- $Z_{RX-HIGH-IMP-DC-NEG}$  and  $Z_{RX-HIGH-IMP-DC-POS}$  are defined respectively for negative and positive voltages at the input of the Receiver. Transmitter designers need to comprehend the large difference between  $>0$  and  $<0$  Rx impedances when designing Receiver detect circuits.
- Defines the time for the receiver's input pads to settle to new common-mode on 2.5 GT/s/5.0 GT/s transition to 8.0 GT/s.
- For voltage  $>500$  mV the effects of Rx ESD structures may limit  $Z_{RX-HIGH-IMP-DC-POS}$  to values less than 20 K $\Omega$ .

Note:

- V<sub>RX-SV-8G</sub> is tested at three different voltages to ensure the Rx DUT is capable of equalizing over range of channel loss profiles. The test also guarantees the Rx is capable of operating over a sufficient dynamic range of eye heights. This “SV” in the parameter names refers to stressed voltage.
- V<sub>RX-ST-8G</sub> and T<sub>RX-ST-8G</sub> are referenced to TP2P and are obtained after post processing data captured at TP2. V<sub>RX-ST-8G</sub> and T<sub>RX-ST-8G</sub> include the effects of applying the behavioral Rx model and Rx behavioral equalization.
- V<sub>RX-SV-DIFF-8G</sub> measurement is made at TP2 without post processing. V<sub>RX-SV-CM-8G</sub> may be made at either TP1 or TP2. V<sub>RX-SV-DIFF-8G</sub> voltage may need to be adjusted over a wide range for the different loss calibration channels.
- T<sub>RX-SV-SJ-8G</sub> and T<sub>RX-SV-RJ-8G</sub> measurements are made at TP1 without post processing.
- Rj is applied over the following range. The low frequency limit may be between 1.5 and 10 MHz, and the upper limit is 1.0GHz. See PCI Express Base Specification Revision 3.1, Figure 4-47 for details.
- V<sub>RX-MAX-SE-SW</sub> sets the maximum outer, single-ended eye voltage limit in the presence of differential and CM noise applied to the Rx, as observed at TP2 relative to ground with no behavioral RxEq post processing.
