1   INTRODUCTION

The PI7C9X3G606GP is a PCIe GEN3 packet switch that supports 6 lanes of GEN3 SERDES in flexible 3-port, 5-port and 6-port configurations. The architecture of the PCIe packet switch allows the flexible port configuration by allocating variable lane widths for each port. The packet switch can be configured to have different port types such as upstream port, downstream ports and Cross-Domain End-Point (CDEP) ports to support various applications, which include port fan-out, dual-host connectivity. Inside the packet switch, multiple DMA channels are embedded to facilitate data communication more efficiently among host(s) and end-points.

In addition, the PI7C9X3G606GP offers some extra benefits such as "maintaining high signal integrity in stress channel", "advanced power management mechanism", "enhanced reliability, availability and serviceability (RAS)" and "Surprised Hot Plug with LED Enclosure Management".

1.1 KEY FEATURES

- Port and Lane Configurations for 6-port/6-Lane PCI Express GEN3 packet switch
  - Configurable Upstream lane widths of x1 or x2
  - Configurable Downstream port number up to 5
  - Configurable Downstream lane widths of x1 or x2
- Reference Clock Management
  - Integrated PCIe Gen3 clock buffer for all downstream ports
  - Support three reference clock structures (Common, SRNS and SRIS)
  - Handle SSC Isolation up to one port
  - Provide two clock application modes (Base and CDSR)
- Power Management
  - Support 7 power states (P0/P0s/P1/P1.1/P1.2/P2/P1.2PG)
  - Start-up power management scheme
    - "Empty" Hot-Plug ports put in P2 state
  - Support Message packet for System Power Management
    - Latency Tolerance Reporting (LTR)
    - Optimized Buffer Flush Fill (OBFF)
- PHY and MAC Layers
  - PHY initial settings optionally programmable through JTAG, EEPROM, and I^{2}C
  - Adaptive Continuous Time Linear Equalizer and 5-tap Decision Feedback Equalizer for RX
  - Adaptive and programmable 3-tap TX equalization
  - RX Polarity Inversion and Lane Reversal
- Data Link Layer
  - Programmable ACK latency timer to respond ACK based upon traffic condition
  - Configurable Flow Control Credit to balance bandwidth utilization and buffer usage
- Transaction Layer
  - Packet forwarding options including Cut-Through and Store & Forward
  - Support up to 512-Byte Max Payload Size
  - Low packet forwarding latency < 150ns (typical case)
  - Access Control Service (ACS) for peer-to-peer traffic
  - Address Translation (AT) packet for SR-IOV application
  - Support Atomic operation
  - Support Multicast
  - Provide Performance Visibility for ingress/egress packet types and packet counts
- Dual-Host Application
  - Support one Cross-Domain End-Point (CDEP) port for Host-to-Host Communications
  - Support Fail-over using CDEP port
  - Provide up to 4 physical or 8 virtual DMA channels enabling communications among Hosts and EPs
- Reliability, Availability and Serviceability
  - Enhanced Advanced Error Reporting
  - End-to-End Data Protection with ECC
  - Error Handling Mechanism
  - Support Surprise Hot Removal
  - Support Downstream Port Containment (DPC)
  - Support Hot Plug for Upstream and Downstream port
  - Provide Serial Hot Plug Type
  - Support LED Management
  - Thermal Sensor reporting operational temperature instantly
  - IEEE 1149.1 and 1149.6 JTAG interface support
- Advanced Diagnostic Tools - PCIBUDDY™
  - PHY Eye™
  - MAC Viewer™ (including embedded LA and LTSSM monitor)

2   GENERAL DESCRIPTION

Similar to the role of PCI/PCIX Bridge in PCI/PCIX bus architecture, the basic function of PCI Express (PCIe) Switch is to expand the connectivity to allow more end devices being reached by host controllers in terms of PCIe serial interconnect architecture. This 6-lane and 6-port PCIe Switch can extend the connections ranged from 2 to 5 PCIe devices by means of its flexible port and lane configurations. It provides users the variety to expand or fan-out the PCI Express lanes from one host based upon their application needs. On top of that, one port of the packet switch can be configured to connect with other host, so that the dual-host usage case can be realized.

In PCI Express system bus hierarchy, the packet switch can be visualized as a logical assembly of multiple virtual PCI-to-PCI Bridge (PPB), which represents either upstream or downstream port. Also, normally all of the primary buses of downstream ports and secondary bus of upstream port are shared with one common virtual PCI Bus. In terms of the port configuration setting in a single host environment, the packet switch PI7C3G606GP can be enumerated with one upstream-port PPB and up to 5 downstream-port PPBs.

The chip adopts a Multiple-Ring as switch core for reaching to each individual port. There are six ports attached to the Multiple-Ring allowing upstream, downstream and peer-to-peer traffic exchanges simultaneously. Each port employs the structure of Combined Input and Output Queue (CIOQ) for buffer management. The main reason for choosing CIOQ is that the required memory bandwidth of input queue equals to the line rate of ingress port rather than increasing proportionally with port numbers as an output queue switch does. The CIOQ at each ingress port contains separate dedicated queues to store posted data, non-posted requests and completion packets. The packets are arbitrated to the egress port based upon the ID or address carried in packet header and PCIe transaction-ordering rule.

Packets can be forwarded in downstream, upstream or peer-to-peer direction concurrently. For the packets without ordering enforcement, they are permitted to pass over each other in cases where the addressed egress port is available to accept them. This can mitigate the issue of Head-Of-Line (HOL) blocking and also not affecting the operation of producer-consumer model, which is required to be retained to prevent from system hang-up problem. On the other hand, the replay buffer at each egress port (output queue) enhances data integrity by preserving the transmitted packets until the appropriate ACK is returned by the link partner. As the out-going packets can be stored in replay buffer,this can gain the maximum throughput and efficiency of the Switch. Another advantage of implementing CIOQ in PCIe Switch is that the credit announcement to the counterpart is simplified and streamlined in terms of the credit-based flow control protocol. The protocol requires that each ingress port maintains the credits independently without checking other ports' credit availability, which is otherwise required by pure output queue architecture.

The Switch supports several advanced features of latest PCI Express specification. They are respectively Access Control Service (ACS), Multi-Cast, Atomic Operation, Alternate Routing ID (ARI), Address Translation (AT) packet forwarding, Latency Tolerance Reporting (LTR) and Optimized Buffer Flush Fill (OBFF) etc. ACS allows the host system to have more control on peer-to-peer switch traffic. This can be a critical requirement in virtual machine system. Multi-Cast is an extended capability of PCIe switch to facilitate posted packets forwarded to a group of downstream ports efficiently. The switch is also capable of being a routing element for Atomic Operation commands, which has the advantages of synchronization among multiple processors or multiple-thread environment. When ARI capability is turned on, the ID routing has an alternative interpretation on Device and Function numbers. The Function number can be increased from 3 bits to 8 bits and no device number any more. This allows the downstream port of packet switch forwarding packets with up to 256 Functions. The LTR and OBFF are message-type packets for communicating between host and end-devices to achieve platform-wise power management. The switch needs to response these two messages for synchronizing the power states of each node in the PCIe interconnect architecture.

In addition to port fan-out function, the PI7C9X3G606GP can be configured to facilitate inter-processor communication between two Processors or between Processor and an intelligent adaptor configured in processor mode. As usual, the upstream port of packet switch is hooked up a host. When configing one downstream port of the switch into CDEP mode, this port will be connected to another host rather than an endpoint. The packet switch then allows these two distinct hosts allocating their own PCIe bus and memory resources and makes the packet transfer happening between them by means of resource translation.

PI7C9X3G606GP supports embedded Direct Memory Access (DMA) capability to move data between two address locations that are set up via DMA channels. There are four physical DMA channels implemented in PI7C9X3G606GP and each physical channel can be shared by two virtual channels. So a total of eight DMA channels can be enabled in the packet switch to enable eight pairs of locations transferring data simultaneously. The DMA engine is configured and managed by a software driver running on the hosts connected to the upstream port or CD ports. In terms of the address locations and DMA ownership, the DMA engines can be used in a variety of applications such as device status collection, peer-to-peer host transfer and peer-to-peer end-point transfer etc.

3   PIN DESCRIPTION

3.1   PCI EXPRESS INTERFACE SIGNALS

NAME	PIN	TYPE	DESCRIPTION
REFCLKP[1:0] REFCLKN[1:0]	L6,A6 L7,A5	I	**Reference Clock Input Pairs:** Connect to 100MHz differential clock source. Please refer to reference clock operational mode for how to connect REFCLKP/N[1:0] to clock sources. The reference clock input is an unterminated AC coupled input. So the off-chip clock source must be terminated with both serial and parallel resistor network. Please refer to PCIe CEM specification for detail on how to realize on-board termination implementation.
RESREF	C6	I	**Reference Resistor Connection:** Attach RESREF an external resistor with the precision of 200 ohm 1% 100-ppm/C to ground on the board. The reference resistor is used for calibration of RX and TX termination when the chip comes out of reset or a manual PHY tuning request is made.
PERP[5:0]	M9,M7,M5,M3,A8,A10	I	**PCI Express Data Serial Input Pairs:** High-Speed Differential data receive signals. Please see the section of port/lane configuration.
PERN[5:0]	M10,M8,M6,M4,A7,A9		
PETP[5:0]	K9,K7,K5,K3,C8,C10	O	**PCI Express Data Serial Output Pairs:** High-Speed Differential data transmit signals. Please se the section of port/lane configuration.
PETN[5:0]	K10,K8,K6,K4,C7,C9		
PERST_L	A12	I	**System Reset (Active LOW):** When PERST_L is asserted, the internal states of whole chip except sticky logics are initialized. This is a global reset to all operational modes of packet switch. This pin has internal pull-up. If no board trace is connected to this pin, the internal pull-up resistor of this pin is enough. However, if pin is connected to a board trace and not driven, it is recommended that an external 5.1K- ohm pull-up resistor be used.

3.2   CONFIGURATION STRAPPING SIGNALS

NAME	PIN	TYPE	DESCRIPTION
CHIPMODE[1:0]	G9,F9	I	**Chip Operational Mode:** These two input signals decide at which operational mode the chip is chosen. | CHIP_MODE[1:0]	Operational Mode

NAME	PIN	TYPE	DESCRIPTION
			330-ohm pull-down resistors.
CKMODE	D9	I	**Clock Operational Mode:** It is used define the relationship between physical SERDES lanes and reference clock. When CKMODE is 0, all 6 lanes (0 ~5) of SERDES are driven by one reference clock source. When CKMODE is 1, 6 lanes of SERDES are driven by two separate reference clock source via two pairs of reference clock inputs. Please refer to reference clock operational mode for connection description. This pin has internal pull-down resistor. If no board trace is connected to these pins, the internal pull-down resistors of these pins are enough. However, if pin is connected to a board trace and not driven, it is recommended that external 330-ohm pull-down resistors be used.
HOT_PLUG_EN_L	*E9	I	**Hot Plug Function Enable:** It is used to determine the downstream port is capable of handling either managed or surprised hot plug events. Besides, the GPIO pins would be redefined for hot-plug function if HOT_PLUG_EN_L = 0. HOT_PLUG_EN_L and FATAL_ERR_L share the same pin. This pin has internal pull-up. If no board trace is connected to this pin, the internal pull-up resistor of this pin is enough. However, if pin is connected to a board trace and not driven, it is recommended that an external 5.1K- ohm pull-up resistor be used.
PM_L11_EN_L	*E1	I	**PM L1.1 Function Enable:** It is used to determine the downstream port is capable of PM L1.1 function. Besides, the GPIO[15:8] pins would be redefined for PM L1.1 function if PM_L11_EN_L = 0. PM_L11_EN_L and INTA_L share the same pin. This strapping pin has no built-in internal resistor and can not be left NC. This pin requires an external 5.1K-ohm pull-up resistor or 330-ohm pull-down resistor.

3.3   HOT PLUG SIGNALS

NAME	PIN	TYPE	DESCRIPTION
SHCL_I2C	L1	OD	**I2C Clock Signal of Serial Hot Plug Controller:** This signal SHCL_I2C is connected to SCL pin of I2C IO expander or CPLD. This pin requires external 5.1K-ohm pull-up resistor.
SHDA_I2C	M1	OD	**I2C Data Signal of Serial Hot Plug Controller:** This signal SHDA_I2C is connected to SDA pin of I2C IO expander or CPLD. This pin requires external 5.1K-ohm pull-up resistor.
SHPCINT_L	M2	I	**Interrupt Input (Active Low) of Serial Hot Plug Controller:** This signal SHPCINT_L is connected to INT# output pin of I2C IO expander or CPLD. When asserted, it notifies Hot Plug Controller to access the port registers of I/O expander or CPLD for touching changed status to de-assert INT#.
HP_LED[7:4;1]	*F1,*H12,*G12,F12,C12	O	**Hot Plug LED:** These signals HP_LED[7:4;1] drive Amber LED state by following SFF-8489 IBPI specification. HP_LED[7:4;1] and GPIO[7:4;1] share the same pins.
HP_RST_L[7:4;1]	*G4,*F3,*F4,*G3,*G2	O	**Surprised Hot Plug Reset:** These signals HP_RST_L[7:4;1] drive reset signals to the hot plug slots. They can be controlled by either off-chip PERST_L when booting up system or internal hardware when device is hot plugged into the slot. HP_RST_L[7:4;1] and GPIO[23:20;17] share the same pins.

3.4   REFERENCE CLOCK OUTPUT AND CONTROL SIGNALS

NAME	PIN	TYPE	DESCRIPTION
REFCLKOP[7:4;1]	C1,B2,B3,A4,A2	O	**Integrated Reference Clock Output Pairs:** 100MHz external differential HCSL clock outputs from integrated reference clock buffer.
REFCLKON[7:4;1]	D1,C2,C3,A3,A1		
CLKREQ_L [7:4;1:0]	*B5,*C5,*C4,*D3,*E4,*E3	OD	**Reference Clock Request Signals:** These signals CLKREQ_L[7:4;1:0] are used to request reference clock for active operation. Each port has its own clock request signal. When asserted, the reference clock is on for both ends of the link. When deasserted, the reference clock is off and both ends of the link are put under L1 sub-state of power management. CLKREQ_L[7:4;1:0] and GPIO[15:12;9:8] share the same pins. CLKREQ_L[7:4;1:0] pins have internal pull-up. If no board trace is connected to these pins, the internal pull-up resistors of these pins are enough. However, if pins are connected to a board trace and not driven, it is recommended that external 5.1K- ohm pull-up resistors be used.

3.5   SIDE BAND MANAGEMENT SIGNALS

NAME	PIN	TYPE	DESCRIPTION
EECK	K12	I/O	**EEPROM Clock:** Clock signal to 4-wire EEPROM interface. **Debug Mode Enable (Debug_Mode_EN_L):** During system initialization, EECK acts as the Debug_Mode_EN_L pin. In debug mode, it need be tired to low through a 330-ohm pull-down resistor. This pin has internal pull-up resistor. If no board trace is connected to this pin, the internal pull-up resistor of this pin is enough. However, if pin is connected to a board trace and not driven, it is recommended that an external 5.1K-ohm pull-up resistor be used.
EEDI	L11	O	**EEPROM Data Input:** The switch outputs data to the Data Input pin of Serial EEPROM.
EEDO	J12	I	**EEPROM Data Output:** The switch inputs data from the Data Output pin of Serial EEPROM.
EECS_L	M11	O	**EEPROM Chip Select (Active Low):** The switch asserts this signal to enable Serial EEPROM.
SCL_I2C	L12	OD	**I2C Serial Clock:** System management or I2C Bus Clock. This pin requires an external 5.1K-ohm pull-up resistor.
SDA_I2C	M12	OD	**I2C Serial Data:** Bi-Directional System Management or I2C Bus Data. This pin requires an external 5.1K-ohm pull-up resistor.

3.6   MISCELLANEOUS CONTROL AND STATUS

NAME	PIN	TYPE	DESCRIPTION
PDC_L[7:4;1]	F2,G1,H1,J1,J2	I	**Present Detect:** When PDC_L is asserted low, it indicates this port is present. Otherwise, it indicates this port is absent. These pins have internal pull-up. If no board trace is connected to these pins, the internal pull-up resistors of these pin are enough. However, if pins are connected to a board trace and not driven, it is recommended that external 5.1K- ohm pull-up resistors be used.
GPIO [23:17;15:12;9:0]	G4,F3,F4,G3,J4,H3,G2,B5,C5,C4, D3,E4,E3,F1,H12,G12,F12,E12, D12,C12,B12	I/O	**General Purpose Input and Output:** These thirty-two general-purpose pins are programmed as either input-only or bi-directional pins by writing the GPIO output enable control register.
FATAL_ERR_L	E9	O	**Fatal Error Output:** It is asserted low when a Fatal error is detected.
INTA_L	E1	OD	**Interrupt Output Enable:** When driven low, it indicates that one or more of the following events/errors are detected: Hot Plug events, Link State events, General-Purpose Input Interrupt events, Device-Specific errors, Device-Specific CDEP Port Link Interface errors and events,

4   FUNCTIONAL OVERVIEW

This chapter provides an overview of the PI7C9X3G606GP's major functions.

4.1   MODES OF OPERATIONS

The PI7C9X3G606GP supports two modes of operations.
- Base Mode (Fan-out Mode)
- Cross-Domain End-Point (CDEP Mode)

4.1.1 BASE MODE (FAN-OUT MODE)

The Base mode is one of the Fan-out mode types. In this mode, the PI7C9X3G606GP supports one upstream port and up to 5 down ports. Multiple virtual PCI-to-PCI bridges are connected by a virtual PCI bus, residing in the Switch.
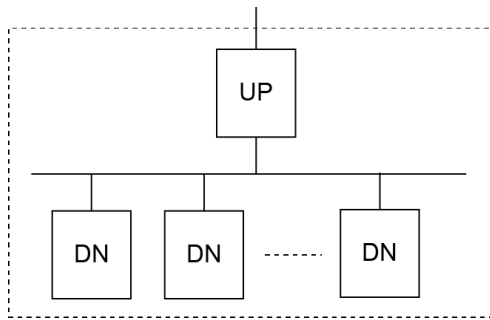

Figure 4-1 Base Mode (Fan-out Mode) Overview

4.1.2 CROSS-DOMAIN END-POINT MODE

The switch supports a Cross-Domain End-Point (CDEP) mode allowing more than one host attached to PI7C9X3G606GP. When configured as CDEP mode, one of downstream port will be turned into CDEP port for additional host to connect with it. So the packets produced from different hosts can exchange through PI7C9X3G606GP for system failover application.

4.2 PHYSICAL LAYER CIRCUITS

The physical layer circuit design is defined as a converter between serial bus interface and the PHY Interface for PCI Express Architecture (PIPE). It contains Physical Media Attachment (PMA) and Physical Coding Sub-layer (PCS) blocks. PMA includes Serializer/ Deserializer (SERDES), PLL1, Adaptive TX and RX Equalization, Clock Recovery module, receiver detection circuit, electrical idle detector, and input/output buffers. PCS consists of two blocks for handling 128B/130B and 8B/10B encoder/decoder, SYNC code-word framer, receiver elastic buffer, and PIPE PHY control/status circuitries. To provide the flexibility for bifurcating multiple lanes into different port width of configuration, the control and status signals of each lane can be combined for MAC to access as a link basis. In addition, a pair of PRBS generator and checker is included for PHY built-in self-test. The main functions of physical layer circuits include the conversion between serial-link and parallel bus, provision of clock source for the Switch, resolving clock difference in receiver end, and detection of physical layer errors.

The driver characteristics including amplitude, and pre-emphasis, on transmit (TX) side are programmable. The PHY on receive (RX) side is capable of automatic calibration and configuration of the internal circuits to maximize receiving performance. In addition, the PHY provides the flexibility for user to override or disable the automatically calibrated settings.

Definition of the Switch Downstream Port's Transmitter presets can be set by LANE EQUALIZATION CONTROL REGISTER (OFFSET from 21Ch – 238h). The encoding for the Transmitter presets is provided in Table 4-1. The Transmitter Preset encoding of 1010b corresponds to the maximum Vtx-boost.

4.2.1 PHY CONTROL REGISTER PARALLEL INTERFACE ACCESS

PI7C9X3G606GP provides the flexibility for user to adjust the transmit swing through the Control Register (CR) Parallel register interface by PCIe link, EEPROM, SMBUS or I2C individually.

The PHY Control Register (CR) Parallel interface is a synchronous, 16 bit data/address parallel port provided for on-chip access to control registers inside the PHY. While access to these registers is not required for normal PHY operation, this interface is included for users that want to override some of the PHY's control signals.

The CR registers can be accessed through PCIe Configuration Registers. The user may access CR RW CTRL and STATUS register in PCIe Configuration Register space to access the PHY Control Register.

The PI7C9X3G606GP is constructed of two tiles. Each of the two tiles is constructed of four PCIe PHYs to support 16 lanes. Each title appears as a separate PCIe bridge device in the system with a single upstream port and multiple downstream port. The Tile ID can be located in Operation Mode register (Offset 348h[2:0]).

All PHY Registers of a given lane in any PHY can be configured through CR Parallel interface via PCI Configuration Registers in upstream port (Port 0): CR RW CTRL AND STATUS register (Port 0, Offset 5C0h), CR CTRL 0 register (Port 0, Offset 5C4h), CR CTRL 1 register (Port 0, Offset 5C8h), CR CTRL 2 register (Port 0, Offset 5CCh) and CR CTRL 3 register (Port 0, Offset 5D0h). The port is a upstream port when the Port Number field is 0 (Link Capability register, Offset 74h[31:24]),

The PHY Control Registers of any one of the 16 lanes can be accessed through the CR CTRL register defined in the table below. A specific lane can be located by enumerating the PHY Number from 0 to 3, and the N Value from 0 to 3.

Table 4-2 PCIe Configuration Registers Used to Access PHY CR Registers

Lane	PHY Number	N Value	PCIe Configuration Register Used to Access PHY CR Register
Lane 0	0	0	CR RW CTRL and STATUS / CR CTRL 0 registers
Lane 1	0	1	CR RW CTRL and STATUS / CR CTRL 0 registers
Lane 2	2	0	CR RW CTRL and STATUS / CR CTRL 2 registers
Lane 3	2	1	CR RW CTRL and STATUS / CR CTRL 2 registers
Lane 4	2	2	CR RW CTRL and STATUS / CR CTRL 2 registers
Lane 5	2	3	CR RW CTRL and STATUS / CR CTRL 2 registers

The packet switch provides CFG registers (offset 5C0h, 5C4h, and 5CCh) to access Qual PHY registers.

4.3   MEDIA ACCESS CONTROL (MAC)

The Media Access Control (MAC) block, which is consisted of physical layer packet boundary delineation and formation, multiple lanes de-skew, scrambler/de-scrambler, clock correction from inserting skip order-set, PIPE-related control/status circuits and Link Training Status State Machine (LTSSM), is implemented to interface physical layer with data link layer, build and maintain the link between two link partners.

The switch allows users to control GEN3 Link EQ parameters and link training behavior such as detection, compliance and lane reverse etc. The switch implements a group of LTSSM CSR registers located at offset starting from 380h to 3A0h to configure LTSSM operation.

4.4   DATA LINK LAYER (DLL)

The Data Link Layer (DLL) provides a reliable data transmission between two PCI Express points. An ACK/NACK protocol is employed to guarantee the integrity of the packets delivered. Each Transaction Layer Packet (TLP) is protected by a 32-bit LCRC for error detection. The DLL receiver performs LCRC calculation to determine if the incoming packet is corrupted in the serial link. If an LCRC error is found, the DLL transmitter would issue a NACK data link layer packet (DLLP) to the opposite end to request a re-transmission, otherwise an ACK DLLP would be sent out to acknowledge on reception of a good TLP.

The moment for issuing ACK DLLP is dependent on a time-out event of ACK latency timer or transmitter channel availability. According to PCI Express specification, the calculation of ACK latency timer is based upon maximum payload size, link width, TLP overhead, ACK factor and internal processing delay. The calculated values are determined by hardware as a default to meet PCIe specified requirement. On the other hand, the chip provides a flexibility to change the value of ACK latency timer by programming the bit 11 ~ bit 0 of DLL CSR registers at offset 420/424/428H for G1/G2/G3 speed. The programmable ACK latency timer can regulate the frequency of issuing ACK DLLP. This can facilitate performance tuning under a burst of TLP in transmission.

In the transmitter, a retry buffer is implemented to store the transmitted TLPs whose corresponding ACK/NACK DLLP have not been received yet. When an ACK is received, the TLPs with sequence number equals to and smaller than that carried in the ACK would be flushed out from the buffer. If a NACK is received or no ACK/NACK is returned from the link partner after the replay timer expires, then a replay mechanism built in DLL transmitter is triggered to re-transmit the corresponding packet that receives NACK or time-out and any other TLP transmitted after that packet.

Meanwhile, the DLL is also responsible for the initialization, updating, and monitoring of the flow-control credit. All of the flow control information is carried in DLLP that is sent to the other end of link. Unlike TLP, DLLP is guarded by 16-bit CRC to detect if data corruption occurs. Furthermore, DLLP is used to handshake protocol between link parties for entering different power states such as PM L1.

The chip implements a group of DLL CSR registers started from offset 420h to 46Ch for users to control the Flow control packet behavior, DLL packet error status report, replay timer and ACK latency timer etc.

4.5   TRANSACTION LAYER RECEIVE BLOCK (TLP DECAPSULATION)

The receiving portion of the transaction layer performs header information retrieval and validates the correctness of the transaction type and format. If the TLP is found to contain an illegal header or the indicated packet length mismatches with the actual packet length, then a Malformed TLP is reported as an error associated with the receiving port. PCIe also supports End-to-End CRC operation to ensure end-to-end data integrity, a 32-bit ECRC is checked against the TLP at the receiver if the digest bit is set in header. Please note for ECRC operation, it is necessary both of EP and RC to support ECRC as well.

4.6   ROUTING

The transaction layer implements three types of routing protocols: ID-based, address-based, and implicit routing. For configuration reads, configuration writes, transaction completion, and user-defined messages, the packets are routed by their destination ID constituted of bus number, device number, and function number. Address routing is employed to forward I/O or memory transactions to the destination port, which is located within the address range indicated by the address field carried in the packet header. The packet header indicates the packet types including memory read, memory write, IO read, IO write, Message Signaling Interrupt (MSI) and user-defined message. Implicit routing is mainly used to forward system message transactions such as virtual interrupt line, power management, and so on. The message type embedded in the packet header determines the routing mechanism.
If the incoming packet cannot be forwarded to any other port due to a miss to hit the desired address range or targeted ID, this is considered as Unsupported Request (UR) packet, which is similar to a master abort event in PCI protocol.

In addition to following standard packet routing rule, the chip also implements a group of TL CSR registers started from offset 4C0h to 4C8h for users to control packet forwarding mode, packet ordering and arbitration scheme etc.

4.7   QUEUE

Six TLP packet types are defined in PCI Express architecture: Memory read/write, IO read/write, Config read/write, Completions, Messages, and Atomic. Each of these packet types fits into the separate switch queues: Posted Request Header (PH), Posted Request Data payload (PD), Non-Posted Request Header (NPH), Non-Posted Data Payload (NPD), Completion Header (CPLH) and Completion Data payload (CPLD). Each packet with different type would be put into a separate queue in order to facilitate the following ordering processor. NPD only contains one DW for all Non-post requests except CAS AtomicOP with 128-bit operand size, which requires two DWs, so it can be merged with the corresponding NPH into a common queue named NPHD.

4.7.1 POSTED REQUEST HEADER (PH)

PH queue provides TLP header spaces for posted memory writes and various message request headers. The types of TLP stored in this queue are MWr, Msg and MsgD. Each header space occupies sixteen bytes to accommodate 3 DW or 4 DW headers. The number of entries in PH range from 8 to 16 depending on the lane width of link.

4.7.2 POST REQUEST DATA (PD)

PD queue is used for storing posted request data. If the received TLP is a posted request type such as MWr or MsgD, and contained payload other than the header, the payload data would be put into PD queue. The size of PD queue ranges from 2KB to 4KB depending on the lane width of link.

4.7.3 NON-POSTED REQUEST HEADER AND DATA (NPHD)

NPHD queue provides TLP header spaces for non-posted request packets, which include memory read, IO read, IO write, configuration read, configuration write and AtomicOP requests. The types of TLP stored in this queue are MRd, MRdLk, IORd, IOWr, CfgRd0/CfgRd1, CfgWr0/CfgWr1, FetchAdd, Swap and CAS. Usually only IO or configuration write and Atomic requests are given additional data credit. The other TLP type is just given header credit. Each header space takes twenty-four bytes to accommodate the following combinations: 3-DW header, 4-DW header, 3-WD header with 1-DW data, 3-WD header with 2-DW data, 4-DW header with 1-DW data and 4-DW header with 2-DW data. In total, the number of entries in NPHD range from 8 to 16 depending on the lane width of link.

4.7.4 COMPLETION HEADER (CPLH)

CPLH queue provides TLP header space for completion packets. The types of TLP stored in this queue are Cpl, CplD, CplLk and CplDLk. Each header space takes twelve bytes to accommodate a 3-DW header. Please note that there are no 4-DW completion headers. The number of entries in CPLH range from 8 to 16 depending on the lane width of link.

4.7.5 COMPLETION DATA (CPLD)

CPLD queue is used for storing completion data. If the received TLP is a CplD or CplDLk type and contained payload other than the header, the payload data would be put into CPLD queue. The size of CPLD queues range from 2KB to 4KB depending on the lane width of link.

4.8   TRANSACTION ORDERING

A set of ordering rules is defined to regulate the transactions on the PCI Express Switch including Memory, IO, Configuration and Messages, in order to avoid deadlocks and to support the Producer-Consumer model. The ordering rules defined in Table 4-2 apply within a single Traffic Class (TC). There is no ordering requirement among transactions within different TC labels. Since the transactions with the same TC label are not allowed to map into different virtual channels, it implies no ordering relationship between the traffic in VC0.

Table 4-3 Summary of PCI Express Ordering Rules

Row Pass Column	Posted Request	Read Request	Non-posted Write Request	Read Completion	Non-posted Write Completion
Posted Request	Yes/No[1]	Yes[5]	Yes[5]	Yes[5]	Yes[5]
Read Request	No[2]	Yes	Yes	Yes	Yes
Non-posted Write Request	No[2]	Yes	Yes	Yes	Yes
Read Completion	Yes/No[3]	Yes	Yes	Yes	Yes
Non-Posted Write Completion	Yes[4]	Yes	Yes	Yes	Yes

1. When the Relaxed Ordering Attribute bit is cleared, the Posted Request transactions including memory write and message request must complete on the egress bus in the order in which they are received on the ingress bus. If the Relaxed Ordering Attribute bit is set, the Posted Request is permitted to pass over other Posted Requests occurring before it.

2. A Read Request transmitting in the same direction as a previously queued Posted Request transaction must push the posted write data ahead of it. The Posted Request transaction must complete on the egress bus before the Read Request can be attempted on the egress bus. The Read transaction can go to the same location as the Posted data. Posted read requests are not allowed to pass posted write transactions due to the concern that if the read and write are to the same location, the subsequent data returned from the read request would be stale data.

3. When the Relaxed Ordering Attribute bit is cleared, a Read completion must ''pull'' ahead of previously queued posted data transmitting in the same direction. In this case, the read data transmits in the same direction as the posted data, and the requestor of the read transaction is on the same side as the completer of the posted transaction. The posted transaction must deliver to the completer before the read data is returned to the requestor. If the Relaxed Ordering Attribute bit is set, then a read completion is permitted to pass a previously queued Memory Write or Message Request.

4. Non-Posted Write Completions are permitted to pass a previous Memory Write or Message Request transaction. Such transactions are actually transmitting in the opposite directions and hence have no ordering relationship.

5. Posted Request transactions must be given opportunities to pass Non-posted Read and Write Requests as well as Completions. Otherwise, deadlocks may occur when some older bridges, which do not support delayed transactions are mixed with PCIe Switch in the same system. A fairness algorithm is used to arbitrate between the Posted Write queue and the Non-posted transaction queue

4.9   PORT ARBITRATION

Among multiple ingress ports, the port arbitration built in the egress port determines which incoming packets to be forwarded to the output port. The switch supports hardware fixed Round Robin arbitration algorithm. The port arbitration is held within the Virtual Channel 0. At the upstream ports, in addition to the inter-port packets, the intra-port packet such as configurations completion would also join the arbitration loop to get the service from Virtual Channel 0.

4.10   FLOW CONTROL

PCI Express employs Credit-Based Flow Control mechanism to make buffer utilization more efficient. The transaction layer transmitter ensures that it does not transmit a TLP to an opposite receiver unless the receiver has enough buffer space to accept the TLP. The transaction layer receiver has the responsibility to advertise the free buffer space to an opposite transmitter to avoid packet stale. In this Switch, each port has its own separate queues for different traffic types (Posted, Non Posted and Completion) and the credits of each type are continually updated via the data link layer on the fly. The data link layer compares the current available credits with the monitored ones and reports the updated credit to the counterpart. If no new credit is acquired, the credit reported is scheduled for every 30 us to prevent the link from entering retrain. On the other hand, the receiver at each egress port gets the usable credits from the opposite end in a link. The egress port notifies the usable credit information to all ingress ports to receive packets that are intended to that egress port.

4.11   TRANSATION LAYER TRANSMIT BLOCK (TLP ENCAPSULATION)

The transmit portion of transaction layer performs the following functions. They construct the all types of forwarded TLP generated from VC arbiter, respond with the completion packets when the local resource (i.e. configuration register) is accessed, and regenerate the message that terminates at receiver to RC if acting as an upstream port.

4.12   ACCESS CONTROL SERVICE (ACS)

Traditionally, the packet routing between the peer-to-peer downstream ports is determined by either the address or ID field embedded in the packet header. Access Control Service (ACS) provides a mechanism for customer to selectively control access between PCI Express Endpoints attached to the downstream ports of packet switch. If ACS is enabled in the ingress port, the peer-to-peer packet forwarding will follow the rule sets of ACS rather than the destination ID or

address. ACS is implemented as a set of capabilities and control registers in the associated hardware component. It brings the following benefits such as preventing the silent data corruption presented in Requests from being incorrectly routed to a peer Endpoint, validating every Request transaction between two downstream components and enabling direct routing of peer-to-peer Memory Requests whose addresses have been translated when ATS system is being used. ACS is usually enabled for directing all peer-to-peer traffic between downstream ports to upstream port.

Please refer to ACS Extended Capability registers at offset 1C0h for more information.

4.13   MULTICAST OPERATION

This is a PCIe optional feature allowing posted packets delivered to multiple endpoints with an efficient way. For some application, more than one target would receive the same packet. By using traditional unicast operation, this packet would be repeatedly transmitted until all targets receive the same packet. The multicast operation would only require one-time transmission to serve all targets. The PCIe spec defines a Multicast Capability structure containing a Multicast address range that is dividable into multiple Multicast Group (MCG) with the size of Multicast Window to enable multicast operation. The multicast address range must be in the same host domain. Multicast is not translated into other host domain address location for cross-domain multicast transactions.

When the incoming packet hits the dedicated MCG within the Multicast address range defined in the ingress port, it will be simultaneously forwarded to the selected egress ports, which have the corresponding MCG bit set in MC_Receive register, if no blocking happens in ingress port. The ingress port also allows the multicast-hit packet being dropped by enabling the corresponding MCG bit in MC_Block_All or MC_Block_Untranslated register.

Please refer to Multicast Extended Capability registers at offset 1D0h for more information.

5.1.3 PORT NUMERING

The port number is given in the port number field of link capability register. Each port has different link width capability, which is also defined in Maximum Link Width field of this capability register. Following table is the port number in the switch and the corresponding maximum link width.

5.2 CLOCK SCHEME

5.2.1 REFERENCE CLOCK OPERATION MODES

The Switch supports two different reference clock operational modes defined by CKMODE. If CKMODE is tied to "0", the Switch sourced from reference clocks is operating under BASE mode. If CKMODE is tied to "1", the switch driven by reference clocks is operating under Cross Domain Separate Reference clock (CDSR) mode. The configured mode determines how the reference clock sources are connected to REFCLKP/N[1:0] input pins.

For example, when the Switch is configured to be in the BASE mode, all of the 6 lanes are driven by REFCLKP/N[0]. In this mode, REFCLKP/N[1] are recommended to be connected to the ground. When the Switch is set to be in CDSR mode, it allows two different reference clock sources to drive these 6 lanes. The users can decide how the reference clocks are connected to the appropriate ports based on the appropriate port lane mapping.

When Switch is configured to be in CDSR mode, chip operates in multiple reference clock domains. In this mode, some of ports work in one reference clock domain while others work in another domain. Each domain can turn on its own SSC function, and the Switch supports SSC isolation feature to allow ports in different SSC domains to transfer packets to each other correctly, given that the frequency differences are within 5600ppm.

The following table illustrates the connections of REFCLKP/N[1:0] in various use cases when CKMODE is set to BASE mode. The reference clock source comes from Root Complex (RC). The clock signal is distributed through buffer or generator to REFCLKP/N[1:0].

Table 5-5 REFCLKP/N[1:0] connections when BASE mode is chosen

Usage Case	REFCLK Architecture	REFCLKP/N[0]	REFCLKP/N[1]
Single Fan-out	Common/ SRNS/SRIS	RC for all ports	GND

If CKMODE is set to CDSR, the use case is similar to dual-host domain. The REFCLK architecture is viewed as in SSC isolation. The Switch can be splitted into 2 host domains with the host port of P0 and P4. These two host ports can be linked at x2 lane-width. The reference clock drives P0 via REFCLKP/N[0], which is the main clock for the entire chip. In this mode, REFCLKP/N[0] is isolated from REFCLKP/N[1], which is connected to P4. REFCLKP/N[0] and REFCLKP/N[1] are sourced differently from the RC_x in their own host domains. The following table illustrates the connection of REFCLKP/N[1:0] in SSC isolation condition.

Table 5-6 REFCLKP/N[1:0] connections when CDSR mode is chosen

Port 0	Port 4	REFCLKP/N[0]	REFCLKP/N[1]
X2	X2	RC	RC_x

5.2.2 INTEGRATED REFERENCE CLOCK BUFFER

The built-in Integrated Reference Clock Buffer of the PI7C9X3G606GP supports five reference clock outputs.

The clock buffer distributes a single 100 MHz reference clock input to five referemce clock output paris, EFCLKOP/N[7:4;1].

The connection of REFCLKOP/N[7:4;1] pins of PI7C9X3G606GP and the reference clock input of downstream port devices have to follow the table shown below if L1.1 is implemented.

Table 5-7 Connection Map for REFCLKOP/N[7:4;1]

Reference Clock Source Pins	REFCLKOP [1] REFCLKON [1]	REFCLKOP[4] REFCLKON[4]	REFCLKOP[5] REFCLKON[5]	REFCLKOP[6] REFCLKON[6]	REFCLKOP[7] REFCLKON[7]
Reference Clock Destination Pins	Downstream Port 1 device	Downstream Port4 device	Downstream Port 5 device	Downstream Port 6 device	Downstream Port 7 device

The REFCLKOP/N[7:4;1] is controlled by CLKREQ_L[7:4;1] pins and internal downstream-port device clock status individually based on L1 PM Substate rule. The output control signals for REFCLKOP/N[7:4;1] are mapped as the following tables.

Table 5-8 Output Control for REFCLKOP/N[7:4;1]

Reference Clock Source Pins	External reference clock source	REFCLKOP[1] REFCLKON[1]	REFCLKOP[4] REFCLKON[4]	REFCLKOP[5] REFCLKON[5]	REFCLKOP[6] REFCLKON[6]	REFCLKOP[7] REFCLKON[7]
Clock Request Control Pins	CLKREQ_L[0]	CLKREQ_L[1]	CLKREQL[4]	CLKREQL[5]	CLKREQL[6]	CLKREQL[7]

The CLKREQ_L[0] is an upstream control signal that should be connected from the switch output with external pull-up to the CLKREQ_L pin on the host chip (Root Complex). The switch combines the CLKREQ_L[7:4;1] and drives the resulting signal out on the CLKREQ_L[0]. When endpoints do not have any packets to transmit, the switch and endpoints will not drive CLKREQ_L[7:4;1], CLKREQ_L[7:4;1] will be high due to external pull-up resistor and the reference clock REFCLKOP/N[7:4;1] for down ports will stop. Then, the switch does not drive the CLKREQ_L[0] low on its upstream port. If the Root Complex does not have any packets requiring transmission, it does not drive the CLKREQ_L[0] either. In this case, the CLKREQ_L[0] will be high due to external pull-up resistor to stop the reference clock source for the upstream port.

If desires to disable some specified Reference Clock Output Paris, it can be done by Port Clock Enable field in the Bifurcation Control Register (offset 55Ch. bit[31:24]) through I2C or EEPROM.

5.3   EEPROM INTERFACE

The EEPROM interface consists of four pins: EESK (EEPROM clock), EEDI (EEPROM serial data input), EEDO (EEPROM serial data output) and EECS_L (EEPROM chip select). The Switch supports 2-, or 3-byte address SPI EEPROM parts and automatically determines the appropriate addressing mode. The EEPROM is used to initialize a number of registers before enumeration. This is accomplished after PERST_L is de-asserted, at which time the data from the EEPROM is loaded. The EEPROM interface is organized into a 16-bit base, and the Switch supplies an 8-bit EEPROM word address.

5.3.1 EERPOM ACCESS MODES

The Switch may access the EEPROM in a WORD format by either utilizing the auto mode through a hardware sequencer or interactive mode through the host configuration commands. For auto mode, it only happens during chip initialization after system reset (Please refer to 5.3.2 for more details). As to interactive mode, it allows to read/write data from/into the EEPROM by giving the command, address and data via EEPROM Control, address and data configuration registers at offset 30Ch and 310h.

5.3.2 EEPROM MODE AT RESET

During a reset, the Switch automatically loads the information/data from the EEPROM if the automatic load condition is met. The first offset in the EEPROM contains a signature. If the signature is recognized, the autoload initiates right after the reset.

During the autoload, the Switch will read sequential words from the EEPROM and write to the appropriate registers. Before the Switch registers can be accessed through the host, the autoload condition should be verified by reading bit [4] offset 308h (EEPROM Autoload Status). The host access is allowed only after the status of this bit is set to '1' which indicates that the autoload initialization sequence is completed.

5.4   I2C INTERFACE

Inter-Integrated Circuit (I²C) is a bus used to connect Integrated Circuits (ICs). Multiple ICs can be connected to an I²C Bus, and I²C devices that have I²C mastering capability can initiate a Data transfer. I²C is used for Data transfers between ICs at relatively low rates (100 Kbps), and is used in a variety of applications. For further details regarding I²C Buses, refer to the *I²C Bus v2.1.*

The Switch is an I²C Slave. Slave operations allow the Switch's Configuration Registers to be read from or written to by an I²C Master, external from the device. I²C is a sideband mechanism that allows the device Configuration registers to be programmed, read from, or written to, independent of the PCI Express upstream Link.
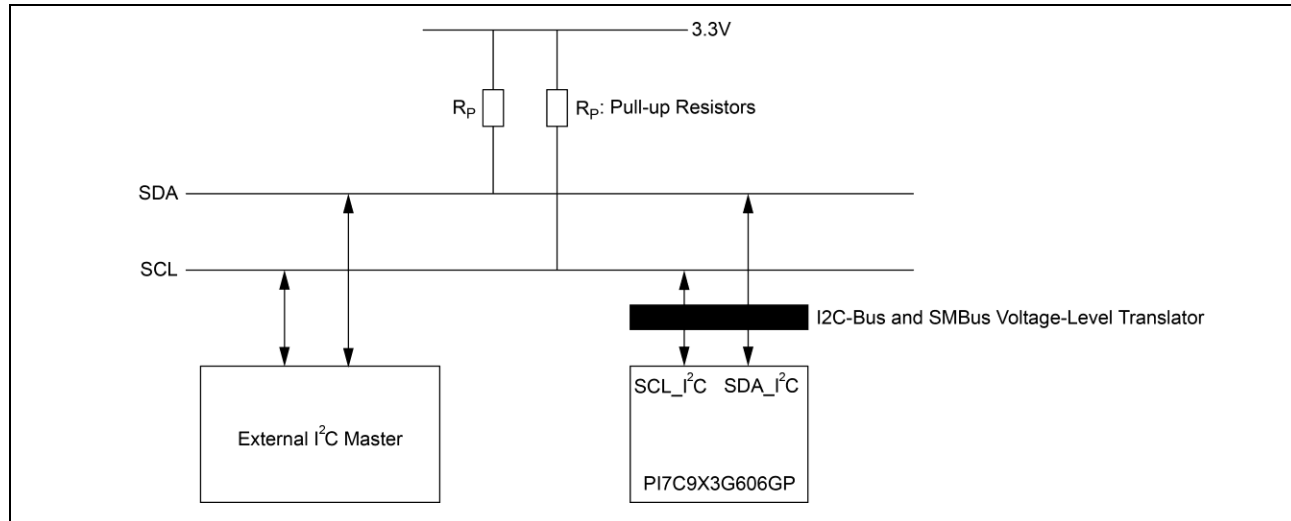

Figure 5-1 Standard Devices to I2C Bus Connection Block Diagram

The I²C interface on the Packet Switch consists of a I²C clock pin (SCL_I2C) and a I²C data pin (SDA_I2C). The I²C clock pin provides or receives the clock signal. The I²C data pin facilitates the data transmission and reception. Both of the clock and data pins are bi-directional. The I²C address pins determine the address to which the Packet Switch responds to. The default setting for the Switch's I²C Slave address is "1101111b", software can change the I2C Slave address, by programming the I2C Control Register's I2C Device Address field (offset 318h.bit[7:1]), through CFG command or EEPROM.

5.4.1 I2C REGISTER WRITE ACCESS

The Switch Configuration registers can be read from and written to, based upon I²C register Read and Write operations, respectively. An I²C Write packet consists of Address Phase bytes and Command Phase bytes, followed by one to four additional I²C Data bytes. Table 5-10 defines mapping of the I²C Data bytes to the Configuration register Data bytes.

The I²C packet starts with the S (START condition) bit. Data bytes are separated by the A (Acknowledge Control Packet (ACK)) or N (Negative Acknowledge (NAK)) bit. The packet ends with the P (STOP condition) bit.
If the Master generates an invalid command， the targeted Switch register is not modified.
The Switch considers the 1st Data byte of the 4-byte Data phase, following the four Command bytes in the Command phase, as register Byte 3 (bits [31:24]). The next three Data bytes access register Bytes 2 through 0, respectively. Four Data bytes are required, regardless of the Byte Enable Settings in the Command phase. The Master can then generate either a STOP condition (to finish the transfer) or a repeated START condition (to start a new transfer). If the I²C Master sends more than the four Data bytes (violating Switch protocol), further details regarding J2C protocol, the Switch returns a NAK for the extra Data byte(s).

Table 5-10 describes each I²C Command byte for Write access. In the packet described in Figure 5-2, Command Bytes 0 through 3 for Writes follow the format specified in Table 5-11.

5.4.2 I2C REGISTER READ ACCESS

When the I²C Master attempts to read a Switch register, two packets are transmitted. The 1st packet consists of Address and Command Phase bytes to the Slave. The 2nd packet consists of Address and Data Phase bytes.

According to the I²C Bus, v2.1, a Read cycle is triggered when the Read/Write bit (bit 0) of the 1st cycle is Set. The Command phase reads the requested register content into the internal buffer. When the I²C Read access occurs, the internal buffer value is transferred on to the I²C Bus, starting from Byte 3 (bits [31: 24]), followed by the subsequent

bytes, with Byte 0 (bits [7:0]) being transferred last. If the I²C Master requests more than four bytes, the Switch re-transmits the same byte sequence, starting from Byte 3 of the internal buffer.

The 1ˢᵗ and 2ⁿᵈ I²C Read packets perform the following functions:
- 1ˢᵗ packet - Selects the register to read
- 2ⁿᵈ packet - Reads the register (sample 2ⁿᵈ packet provided is for a 7-bit Switch I²C Slave address)

Although two packets gare shown for the I²C Read, the I²C Master can merge the two packets together into a single packet, by not generating the STOP at the end of the first packet (Master does not relinquish the bus) and generating REPEAT START.

In the packet described in
Figure **5-5**, command Bytes 0 through 3 for Reads follow the format specified in Table 5-12

6   HOT PLUG SUPPORT

The hot plug usages can be classified into surprised and managed types depending on the application scenario. The switch implements both surprised/managed serial hot-plug types in the downstream ports. The HOT_PLUG_EN_L strapping pin should be set to "0" to enable hot plug function in the downstream ports of the switch.

6.1   HOT PLUG TYPES

6.1.1 SURPRISED SERIAL HOT PLUG

If the device is inserted or removed asynchronously from downstream port, it is called surprised hot plug. When Hot-Plug Surprise bit in Slot Capability Register is set to "1", the chip is operating under surprised hot plug mode.

- Hot Insertion Procedures:
    - Present Detect Pin (i.e. PDC_L[7:0]) is asserted
    - The corresponding "Presence Detect Change" and "Present Detect State" in slot status reflect the card is in the slot
    - Enable the corresponding reference clock output (i.e. REFCLKOP/N[7:4;1]) to the hot inserted device
    - Issue INTx Message or MSI to notify software processing hot plug event
    - Wait for 628 ms and then deassert the corresponding downstream reset (i.e. HP_RST_L[7:0])
    - If DL_UP is set, then generating INTx Message or MSI to notify software initiating configuration cycles to the hot inserted device

- Hot Removal Procedures
    - The device is removed asynchronously or under abnormal condition (Ex. Human Error …)
    - Either in-band or out-band Present Detect sensing device being removed
    - Commands LTSSM state machine to Detect.Quiet state
    - Upstream port replies UR status that any TLP being sent to this downstream port
    - Any packet stored in input queue of upstream port will be dropped silently
    - Assert Present detect change Interrupt to system software
    - Enable DPC trigger event and assert DPC interrupt and unmasked non-fatal message to system software
    - Turn off the corresponding output clock buffer and assert the corresponding hot plug reset signal

During power-up, the chip scans IO Expander like devices through I2C clock and data signals (i.e. SHCL_I2C and SHDA_I2C). According to the reference design described in LED management, one set of I2C bus serves 4 CPLD, which converts the serial bus into 8-bit parallel bus. The 8-bit mapping is defined in Table 6-1.

Table 6-1 CPLD Signal Name Mapping for 8-bit IO Expander

BIT	DIRECTION	CPLD SIGNAL NAME
0	O	FAULT
1	O	LOCATE
2	N/A	Not used (Debug Only)
3	N/A	Not used (Debug Only)
4	I	PRSNT_L
5	N/A	Not used (Debug Only)
6	N/A	Not used (Debug Only)
7	N/A	Not used (Debug Only)

Among these signals, ATNLED and PWRLED defined in PCIe specification are repurposed to represent FAULT and LOCATE to be compliant with SFF-8489 for blinking LEDs. For details, please refer to LED Management specification.

The switch hot plug controller supports multiple I2C-like control interfaces. Each interface can serve up to 8 downstream ports. The I2C address for slave devices is started from 40h by default. In addition, this initial address is configurable through EEPROM to registers LTSSM/IOE CSR6 Bit[30] and LTSSM/IOE CSR7 Bit[6:0]. Each downstream port is correspondent to one equivalent 8-bit IO expander with the following Port/Address mapping table.

Table 6-2 Port/Address Mapping for 8-bit IO Expander

6.1.2 MANAGED SERIAL HOT PLUG

If the device is inserted or removed synchronously with hot-plug management software from downstream port, it is called managed hot plug. When Hot-Plug Surprise bit in Slot Capability Register is set to "0", the chip is operating under managed hot plug mode.

- Hot Insertion Procedures:
  - User inserts card
  - User closes MRL
  - User initiates hot-inserted sequence by pressing Attention Button
  - System commands slot control register to drive indicators and power on slot
  - System starts re-enumeration the hierarchy under the slot

- Hot Removal Procedures:
  - User initiates hot-removed sequence by pressing Attention Button
  - System informs application/driver to complete current task
  - System commands slot control register to drive indicators and power off slot
  - System disabled the hierarchy under the slot
  - User opens MRL and removes the card

During the process of hot insertion and removal, there are hot plug events corresponding to slot status bits ready for generation. When Hot-Plug Interrupt Enable bit is set, either MSI or INT message is issued to notify S/W for processing.

When power-up, the chip uses I2C clock and data signals to scan either 16-bit or 40-bit IO Expander dependent on the status of strapping pin (i.e. IO_EXP_TYPE). The IO Expander responds an interrupt (i.e. HPCINT_L) to notify any hot plug signal status change and the chip will read back the status change in serial mode and reflect on slot status register. The 16-bit mapping of managed hot plug events for I2C bit sequence is defined in Table 6-3

6.2   TIMING SEQUENCE FOR SURPRISED HOT PLUG OPERATION

Two timing charts are shown below to illustrate surprised hot insertion or removal under different scenarios. The first chart presents the timing relationship between system reset/reference_clock and individual downstream reset/reference_clock under initial power-up condition. The second chart demonstrates the timing sequence of clock and reset for device inserted or removed under power active condition.

7   CROSS-DOMAIN END-POINT

7.1   GENERAL DESCRIPTION

The PCIe Packet Switch supports Cross-Domain End-Point (CDEP) function. The function, when working in conjunction with the software running on the Main Host, enables data exchange among multiple PCIe-based hosts. This feature allows the system to implement fail-over or co-processor functionalities. These two use cases are briefly described in the following sections with the suitable CDEP Mode Switch Model for the use case.

7.1.1 FAIL-OVER

In an error resilient system, a Remote/Back-up Host is set up to take over the Main Host in the event when Main Host has failed and the failure is detected. The CDEP Mode Switch Model facilitates the data exchange across domains of the Main and Remote/Back-up hosts, and swaps the roles of the hosts in the event of the Main Host's failure. The CDEP Mode Switch Model used in the fail-over use case is shown in the illustration below.
Figure 7-1 Switch Reference Model Used in the Fail-Over Use Case

In the event when the Main Host is unable to send regular messages to the Remote/Back-up Host, the Remote/Back-up Host can swap its role to the Main Host and its CDLEP port being a agent of upstream port to handle the traffic to/from downstream ports. . The previous Main Host's upstream port will be reset during the link-down process initiated by the previous Main Host. The Switch has to ensure that the reset does not propagate to the entire upstream hierarchy in the previous Main Host's, so that the new Main Host can seamlessly manage the original End-Points. As a result, the impacts to the entire system are minimal during the fail-over transition.

7.1.2 CO-PROCESSOR

The Remote Host/Co-processor can be connected to the CDLEP port to off-load the computation on the Main Host. The illustration below shows a Remote Host/Co-processor unit (CP), which works with the Main Host to form a two-processor system. The DMA function of the Main Host's upstream port is enabled to move data among the Main Host and Remote Host/Co-processor to accelerate intensive computation tasks.

7.2 PORT CONFIGURATION

The Main Host can configure a link CDEP port as a generic PCIe End-Point. This allows the Remote Host(s) the ability to link to the switch CDEP port during PCIe enumeration. The enumeration process includes BIOS start-up, operating system start-up, and/or subsequent PCIe hot-plug or dynamic enumerations initiated by the host operating system.

Before the Main Host can enable the CDEP function, the Switch has to be configured into the CDEP mode and designate the CDEP port to as the upstream port of a generic end-point. The configuration is performed through EEPROM programming at power-up. In order to operate in the CDEP mode, the Switch is required to set Chip CD Mode and Switch CD Mode for the CDEP port configurations. The Chip CD Mode and Switch CD Mode are defined in the Device Configuration 0 and 2 Registers respectively.

In order to support the CDEP mode, the Switch has to contain a Cross-Domain Virtual End-Point (CDVEP). The CDVEP acts as an agent to bridge the Main Host and other host domain, and only exists in the Switch.

In addition to the CDVEP, the Switch has another type of End-Point, called Cross-Domain Line End-Point (CDLEP). The CDLEP is visible to the Remote Host (RH), but not the Main Host. The CDLEP bridges the communications between the Remote Host and other HOST. The table below describes the CDEP port's configurations by the Switch types.

Table 7-1 CDEP Mode Configuration

Switch CD Mode	CDEP Configuration
0x	Both CDEPs disabled
10	Illeagal Configuration
11	CDVEP enabled, and CDLEP enabled

Only P4 can be designated as a CDLEP port.. Once the ports are chosen as CDLEP ports, the port numbers defined in Link Capability Register and MMIO Register offsets will be changed accordingly.

7.3 BAR TRANSLATION FOR REMOTE HOST DOMAIN

The Main Host configures a set of CDEP Link address translations to the Switch. The translations allow the Remote Host to access the CDEP Link's 64-bit BAR2/BAR3 and BAR4/BAR5 similar to accessing the other HOST locations. The Main Host software is responsible for managing the memory regions appropriately to implement and emulate the CDLEP end-point behaviors.

The Main Host defines either or both of a Direct Address Translation (DAT) range, and an Address Look-up Table (ALUT) for the BAR translations for the Remote Host to access to other HOST memory locations. The Main Host

configures these settings prior to enabling the CDLEP port. After the Main Host programs the CDLEP port's BARs, the Remote Host is able to read/write to the Main Host or other Remote Host memory locations.

7.3.1 DIRECT ADDRESS TRANSLATION (DAT)

The Main Host arranges a contiguous memory block in the Remote Host domain by setting BAR Configuration registers with the chosen DAT. The BAR2/BAR3 and BAR4/BAR5 have their own corresponding contiguous memory blocks. These memory blocks are characterized by the Base bits and Window Size bits. If the upper address of incoming TLP matches with the Base bits, the upper address will be replaced with the translated address stored in Base Translation Registers (BTR2/BTR3 and BTR4/BTR5). The lower address bits are defined by the Window Size bits and remain intact. They are considered to be an offset address from the base address. The Window Size is determined by the BAR configuration, and the minimum size is 1MB.

7.3.2 ADDRESS LOOK-UP TRANSLATION (ALUT)

In addition to the Direct Address Translation, the BAR2/BAR3 provides an alternative address translation mechanism, Address Look-Up Translation (ALUT). The ALUT allows multiple translated address blocks in a non-contiguous address range. The Window Size bits defined earlier can be partitioned into 7 index bits and the rest lower address bits can form Page Size bits. The minimum page size is 8KB (1MB divided by 128). The 7 index bits are used to access 128 entries. Each entry represents a translated address block and the host domain destination it is associated with.

The ALUT Access Control Registers at offset from 918h to 920h in the CDLEP is used to store 128 entries. When performing ALUT entry write, the software has to program the ALUT data into the CDLEP at offset 91Ch and 920h if the translated address is 64-bit. The software then updates the index and Command (set to write) fields of the CDLEP at offset 918h. When performing LUT entry read, the software has to program index and Command (set to read) fields of the CDLEP at offset 918h, and then read 91Ch and 920h to get the LUT data.

7.3.3 ID TRANSLATION

In the event when a PCIe read or write is initiated in the Remote Host PCIe domain, and the read/write targets the Main Host memory or an end-point in the Main Host PCIe domain, the PCIe Requestor ID field in the TLP header that targets the Main Host must be *translated* into the PCIe Requestor ID of the CDVEP. This is to ensure that the IOMMU access permissions granted by the Main Host operating system, virtual machine, and/or end-point driver, apply to these translated TLPs. If the target is to another Remote Host PCIe domain, the PCIe Requestor ID has to be translated into the PCIe Requestor ID of the destination CDLEP to ensure that a legal ID is used by the destination Remote Host system. The domain id of the Main Host is 0. That of the Remote Host is 1.

7.4   BAR TRANSLATION FOR MAIN HOST DOMAIN

The Main Host also configures a set of CDEP Virtual address translations. The address translations allow accesses to a defined address range to be translated to the Remote Host memory addresses.

Similar to BAR Translation on the Remote Host domain described previously, the BAR Translation on the Main Host domain also supports two different approaches: the Direct Address Translation and the Address Look-Up table Translation. Please refer to the section of CDVEP CONFIGURATION REGISTERS for related BAR translation setup registers such as BAR Configuration, BTR, ALUT Access Control, and more.

The RID translation in Main Host domain is the same as the translation in the Remote Host domain. The only difference is in building the RID LUT. However, the RID table is programmed by the Main Host in the default setting, not by hardware automatically.

7.5   SCRATCHPADS AND DOORBELLS

The CDEP Link and virtual interfaces may provide a set of switch-specific scratchpad and doorbell registers for uses in Remote Host-to-Main Host/Host communication. By definition, custom driver or diagnostic code is required to run on the hosts. As a result, the Main Host or Remote Host must determine their visibility when a CDEP port emulates a generic End-Point. The registers must appear in PCIe configuration space in user-defined regions.

If the Main Host intends to make the scratchpad and doorbell registers visible to the host, the Main Host should define a CDEP Link property that enables a non-prefetchable 32-bit BAR0 containing these scratchpad and doorbell registers. A 4K range is allocated for CDLEP within the BAR0 at an offset address defined in the table in section 9.2.3 of the register reference document

In each CDLEP or CDVEP, there are 8 sets of 32-bit scratchpad registers (CDLEP at offset 9E4h~A00h, and CDVEP at offset 9E4h~A00h), and one set of 32-bit doorbell registers (CDLEP offset 9C4h~9D0h and CDVEP offset 9C4h~9D0h). The scratchpad registers are used to store information for communication among Remote Hosts and Main Host. The doorbell registers are utilized to process (set/clear/mask/unmask) interrupt in order to notify the destination host to fetch the data stored in scratchpad registers of the source host. The scratchpad registers can only be written by the host in same domain while doorbell registers can be set/clear by both of hosts either in the same domain or in different domain. If the Main Host uses the PCIe configuration command to access scratchpad and doorbell registers, it keep track of its End-Point-defined region and restrict its range so it does not go over the offset 9C4h. If the memory commands are used to access these registers in the CDLEP, the Main Host has to enable a non-prefetchable 32-bit BAR3. A 4K range is allocated for CDLEP within the BAR0/1 at an offset address defined in the address table of Device Specific Memory Mapped Configuration Mechanism.

8   DIRECT MEMORY ACCESS

8.1   GENERAL DESCRIPTION

The Switch provides two DMA engines. These are hardware blocks that includes a set of buffers to asynchronously read and write to I/O memory through the Switch's ports. Each DMA engine is configured through a corresponding PCIe Function, managed by a software device driver running on a connected Remote Host (RH) or Main Host (MH). The DMA engine is divided into single or multiple physical channels (2 per engine), providing a reserved portion of the buffer pool, and access to a set of virtual channels (2 per physical channel). The virtual channels allow the software initiator to submit lock-free requests, or partition access to the channel among a set of cooperating software subsystems. The initiator accesses the DMA engine using a physical/virtual channel (hereafter abbreviated as channel) to submit descriptors. Each descriptor tells the engine to read from a DMA source into one of the channel's internal buffers, and then performs a corresponding write to a DMA destination.

The Switch's DMA engines can be configured in a variety of ways, including:
- Device Status Collection: A host CPU can off-load blocking MMIO reads of device status registers to the DMA engine for asynchronous processing.
- Peer-to-Peer EP Transfer: A host CPU can off-load memory copies between a set of managed devices in the Switch.
- Peer-to-Peer Remote Host Transfer: A set of cooperating Remote Hosts connected through a pair of CDEP ports can use the DMA Engine as a RH-to-RH memory transport, implementing a message queue.

In this section, any description of register layouts and data formats uses little-endian ordering.

8.2   DMA CONFIGURATION

The Switch's EEPROM or a micro-controller connected via I2C interface first configures the Switch's DMA engines (functions), enabling the DMA functions to appear underneath appropriate ports. Then, the software attaches a DMA driver to the DMA function based on the software model for the switch deployment to initialize and manage the set of channels (descriptor queues), start/stop/restart the channels, and perform appropriate error handling.

8.2.1 DMA FUNCTIONS

The Switch's EEPROM and switch configuration registers are set to indicate the ports under which the DMA functions will be visible to the connected RH or MH. This may include upstream ports, CDEP Link Ports, or virtual upstream ports.

The Device Configuration #2 Register (offset 50Ch) defined in upstream port (Port 0) is used to configure DMA function (Bit [19:18]) under various CD modes (Bit [17:16]) (Please refer to CDEP chapter for CD mode definition). The DMA mode definition is represented by the following table.

Table 8-1 DMA Mode definition

DMA Mode	DMA Configuration
0x	DMA functions disabled
10	DMA functions enabled for P0 or P4 based upon CD mode
11	DMA functions enabled for P0 only

8.2.1.1   DMA MODE BIT DEFINITION

- Bit #1: Decides if DMA function is enabled in the port connected to RH or MH.
  0: DMA function is disabled
  1: DMA function is enabled

- Bit #0: Determines if DMA function only visible to the MH's domain
  0: DMA function is visible to its own remote host or the MH's domain
  1: DMA function is only visible to the MH's domain

8.2.1.2   DMA MODE AND CD MODE

DMA function is defined in the various ports under different CD and DMA mode settings. These ports are respectively "P0 port" and "CDLEP port". A comprehensive table as shown below illustrates how the DMA functions (F1 or F2) being assigned to these three types of ports in terms of CD and DMA modes.

Table 8-2 DMA Function Definition in P0 and CDLEP Under Various Modes

11	01	Up-Port*	N/A	CDLEP	N/A
11	10	Up-Port*	1 DMA	CDLEP	1 DMA
11	11	Up-Port*	2 DMAs	CDLEP	N/A

Note: Up-Port* means that CDVEP exists in the Up-Port host domain

8.2.1.3   ENUMERATION

The PCIe configuration space for each port that has been configured for DMA will enumerate one or more DMA Functions (Type0 configuration space headers), with a well-defined vendor, device, and class code indicating DMA, and a set of control registers associated with a non-prefetchable BAR. Software will enumerate each DMA Function and program BARs. These configuration registers for function #1 or function #2 is defined in the chapter 9 of this document.

8.2.2 DMA CONTROL REGISTER

DMA engine (i.e. function) provides a set of interface registers for software to control the operation and monitor the status of DMA transfer for all channels managed by this function. These registers are accessed by mmio via a base address defined in non-prefetchable BAR0 and BAR1 registers associated with the channel and individual register

offset defined in the section 5 of this document. For each channel, it will add an additional 100h offset to indicate the interface registers of one channel located in a 256-byte block. Hence, the access to one particular interface register in one of channels requires to set the address offset as follows: register offset + (number of channel) x 100h. Software can check the Channel ID field (Bit 31:28) of DMA Control and Status Register 0 at offset 00h to see if it is accessing the desired channel.

8.2.2.1   DMA DESCRIPTOR REGISTER

The DMA control register space will include a 64-bit pointer to the i/o address base of each channel's descriptor ring, and the size of the descriptor ring. Software will program the DMA registers to configure each descriptor ring, from which a channel will prefetch. The channel will support a total size for each descriptor ring of at most 4096 entries.

8.2.2.1.1   DESCRIPTOR POINTER REGISTER

The I/O address base of each channel's descriptor ring is pointed by a 64-bit channel descriptor ring base pointer at register offset 0Ch and 10h. The software has to program these registers, so the hardware can prefetch the descriptors starting from there.

8.2.2.1.2   DESCRIPTOR SIZE REGISTER

The size of descriptor ring can be programmed in register offset 24h (Bit 12:0 in Channel Descriptor Ring Size for Prefetch register). The maximum descriptor ring size is 4096 entries. The Bit 28:16 of this register indicates the next descriptor index is going to be prefetched.

8.2.2.2   DMA OPERATIONAL REGISTER

The DMA control register space will include a control register (DMA Control and Status Register 1 at register offset 20h) for each channel to start, stop, abort, pause, and resume DMA activity for the channel. Software will update the control register to start the engine once it is ready to begin submitting requests. Software will update the control register if it needs to pause, stop, or otherwise reconfigure a channel.

After starting the DMA activity for that virtual channel (i.e. write "1" to Bit 0 of DMA Control and Status Register 1), the software can update the control register any time by commanding the DMA engine to pause, abort or stop operation. Following is a summary for these three operations.

8.2.2.2.1   PAUSE (BIT 1)

When set, the DMA activity is paused to the next active descriptor after completing the processing on current descriptor. Then, the DMA Pause Done status (Bit 16) is turned on to represent the DMA is in "paused" condition. If DMA Pause Interrupt Enable (Bit 3) is set, an interrupt will be issued to notify the software when Bit 16 is set. For pause operation, there is no any descriptor or data being dropped and the DMA operation can be resumed any time by clearing the Pause Control (Bit 1).

8.2.2.2.2   ABORT (BIT 2)

When set, the DMA activity drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data. The pointer will move to the next active descriptor. Then, the DMA Abort Done status (Bit 17) is turned on to represent the DMA is in "aborted" condition. If DMA Abort Interrupt Enable (Bit 6) is set, an interrupt will be issued to notify the software when Bit 17 is set. In abort condition, the DMA operation can be resumed any time by clearing the Abort Control (Bit 2) and setting DMA Start (Bit 0). Then, DMA begins to process the next active descriptor. In fact, the software is also allowed to reprogram interface registers for re-initialization and start from the base descriptor pointer.

8.2.2.2.3   STOP (BIT 7)

When set, the DMA activity drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data. The channel interface registers are all cleaned to default state except Interrupt flag bit if DMA stop enable is set earlier. Then, the DMA Stop Done status (Bit 18) is turned on to represent the DMA

is in "stopped" condition. If DMA Stop Interrupt Enable (Bit 5) is set, an interrupt will be issued to notify the software when Bit 18 is set. In stop condition, the data buffer contents pointed by the previous processed descriptor will be dropped as well, so the software needs to reprogram interface registers for re-initialization before resuming DMA activity by setting DMA Start (Bit 0).

8.3   DMA DESCRIPTORS AND TRANSFERS

Each DMA channel will initiate descriptor pre-fetch when the channel is enabled and its ownership register is updated, indicating the valid range of descriptors to prefetch. When a valid descriptor is found, a DMA transfer will be scheduled with the underlying DMA engine in a fair manner with respect to other descriptors from other channels. The descriptor will be re-written by the DMA engine when the DMA transfer is complete, or if the DMA transfer fails due to an error. The switch will also update the ownership register to indicate the range of completed descriptors. Software will then examine the completed descriptors and take appropriate action.

8.3.1 DESCRIPTORS

Descriptors are located in the system memory. All of descriptors in a ring have to be concatenated together without gap (see figure 1. below). The switch will calculate the address offset automatically by adding the index of descriptor multiplied with the byte count of a single-descriptor to the ring base descriptor pointer for prefetch.
Figure 8-1 DMA Descriptor Map

8.3.1.1   INITIALIZATION

Software will initialize a valid descriptor by writing it to memory at the next free location in a channel's descriptor ring. Software will ensure that the descriptor's valid bit is written only after all other descriptor fields have been initialized. Software will update the ownership register to schedule execution of all initialized descriptors with the DMA engine.

8.3.1.2   OWNERSHIP

After all descriptor fields have been initialized, Software will update the ownership registers located at the register offset 04h and 08h by setting valid status. The descriptor ownership 0 register (04h) represents the first 32 descriptors' valid status starting from bit 0 while the descriptor ownership 1 register (08h) stands for the next 32 descriptors' valid status. The switch will pre-fetch the descriptors with valid status turned on continuously until the descriptor with valid

status being cleared. After the descriptors have been processed, the switch will update the ownership registers by clearing valid status in the order it was received.

8.3.1.3   PRE-FETCH

Software needs to update the Channel Descriptor Ring Size for Pre-fetch register at offset 24h by writing total descriptor numbers into Bit 12:0. Starting from the 1st descriptor pointed by ring base pointer register (0Ch and 10h), the descriptors will be pre-fetched by the switch continuously. The Channel Descriptor Current Pointer register at offset 14h indicates which descriptor is under processing. The switch will also take a residual function over the descriptor numbers divided by 64. If the remainder is less than or equal to 64, the switch will go back to prefetch the 1st descriptor after hitting the last descriptor.

When Software prepares to update the ownership registers during the DMA operation, it requires to check Descriptor current pointer (14h) viewed by the switch in order to update the correct 64-bit sliding window, which is advanced in terms of descriptor units.

8.3.2 TRANSFER

Software will define in the descriptor a 64-bit i/o source address, 64-bit i/o destination address, and transfer length up to 8MB. Switch will divide the DMA transfer into appropriate pairs of Memory Read and Write TLPs based on the current switch settings for Max_Payload_Size and Max_Read_Request_Size, along with any 4k boundaries crossed by the range of addresses. Other than 64-bit i/o source and 64-bit i/o destination address, Software will also define 4-bit source domain and 4-bit destination domain in the descriptor for moving data across domains. Switch needs to generate Read or Write TLPs with a translated RID if the TLP destined domain is different from the domain where the DMA function is located.

8.3.2.1   LOCAL DOMAIN TRANSFER

For a local DMA transfer (i.e. no crossing host domains, the SDV and DDV must be "0" in the CTRL word of descriptors), the switch will refer to Max_Payload_Size and Max_Read_Request_Size defined in PCIe configuration space in where the DMA function is resided for generating MRD and MWR TPLs along with any 4k boundaries crossed by the range of addresses.

8.3.2.2   CROSS DOMAIN TRANSFER

As to a cross-host-domain DMA transfer (i.e. either SDV or DDV or both are "0"), the switch will refer to Max_Payload_Size and Max_Read_Request_Size of other host domains defined in register offset 28h, 2Ch and 30h, which are usually programmed by Main Host. The switch will check the domain id carried in descriptor to choose the appropriate Max_Payload_Size and Max_Read_Request_Size for creating MRD and MWR TLPs. Please note that the Main Host software has to program the correct values of Max_Payload_Size and Max_Read_Request_Size for each domain by following the definition in PCIe configuration device control registers of that domain. Otherwise, it will cause undesired result in packet transfers.

As the DMA transfer source domain is different from destination domain, the Requester ID needs to be translated into a legal BDF ID of the destination domain. The software is required to program the captured bus number of CDV or CDL into domain bus number defined in register offset 34h, 38h and 3Ch. Regarding the captured bus number, the software can refer to CDEP data 0 register at offset A04h of CD port. The switch will check the domain id carried in descriptor to choose the appropriate bus number for creating RID of MRD and MWR TLPs.

8.3.3 DESCRIPTOR LAYOUT

The descriptor is formed by an 8-DW data block. The Figure 2 (see below) presents the layout of these DWs containing control word, source domain/address, destination domain/address, transfer byte count and others.
Figure 8-2 DMA Descriptor Layout in an 8-DW block

8.3.3.1 DOMAIN AND ADDRESS FIELD

The 64-bit I/O destination address and source address are located from the 3rd DW to 6th DW. They must be D-Word aligned. Also in the 7th DW, it defines the destination domain id (Bit 7 ~ Bit 0) and source domain id (Bit 15 ~ Bit 8) used for cross-domain DMA operation. Each domain id is expressed by LSB 4-bit that represents for 12 different host domain (0 ~ 1) supported by one packet switch. As to MSB 4-bit, they are reserved for future use.

8.3.3.2 TRANSFER COUNT FIELD

The bit 22 ~ bit 0 in the 2nd DW stands for the transfer byte count for one descriptor can be up to 8MB.

8.3.3.3 CONTROL FILED

There are several bits defined in CTRL field of 1st DW for further formatting and enabling the source and destination locations. Please see Table 3 for illustrating bit definition in CTRL filed.

Table 8-3 Bit Definition in CTRL Field of the 1st DW

Bit	Name	Description
31	EOT	End of transfer
30	INT	Issue interrupt when DMA done
29	TPH	TPH function enable
28	NOP	No operation
27	FLH	Dlush any cached data
26	SAV	Source address is valid
25	DAV	Destination address is valid
24	64bit	Rnable 64 bit address
23	SAV	Source domain is valid
22	DDV	Destination domain is valid
21	CRC	Enable CRC checksum

◇ EOT(End of Transfer): Defined in bit-31. When set, it indicates the current DMA transfer is completed. The interpretation on EOT is various for different DMA modes. If the EOT valid bit defined in the DMA control register 0 is set, the switch will update the EOT bit in descriptor from 0 to 1 after transfer count indicated in descriptor is ended.

◇ 64bit: Defined in bit-24. When set, the I/O address is in 64-bit physical memory. Otherwise, it is in 32-bit physical memory.

◇ SAV: Defined in bit-26. When set, it means the I/O source address is valid. If cleared, the I/O source address is not valid, which is the condition that only destination DMA channel is enabled for executing host to host DMA.

◇ DAV: Defined in bit-25. When set, it means the I/O destination address is valid. If cleared, the I/O destination address is not valid, which is the condition that only source DMA channel is enabled for executing host to host DMA.

◇ SDV: Defined in bit-23. When set, it means the source domain id is valid and MRD will be issued to that domain by following its max payload size and read request size. It implies that DMA source and DMA function (or descriptors) are located in different domains. If cleared, it might be in the condition of either only DMA destination is positioned in a different domain from DMA function or just for a local (i.e. same domain) DMA transfer between source and destination.

◇ DDV: Defined in bit-22. When set, it means the destination domain id is valid and MWR will be issued to that domain by following its max payload size. It implies that DMA destination and DMA function (or descriptors) are located in different domains. If cleared, it might be in the condition of either only DMA source is positioned in a different domain from DMA function or just for a local (i.e. same domain) DMA transfer between source and destination.

◇ NOP: Defined in bit-28. Software can configure a no-op (zero length) descriptor by setting NOP of CTRL field. Once this bit is turned on, that performs no Reads or Writes. and

◇ FLH: Defined in bit-27. Software can configure a cache flush descriptor by setting FLH of CTRL field. A cache flush descriptor, that forces the DMA engine to flush its buffer cache, and cancel any outstanding DMA Reads (thereby avoiding lengthy Completion Timeout conditions). Once this bit is turned on, the DMA activity drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data. The channel interface registers are all cleaned to default state as well. Software can check if DMA Start (Bit 0 of register at offset 20h) is cleared to ensure "flush" event has completed. This "flush" feature provides a way for Software to restart DMA operation in terms of reinitializing the DMA ring buffer and interface registers.

◇ INT: Defined in bit-30. Software may configure a descriptor with a flag (setting INT of CTRL field) to interrupt the software device driver on the completion (or failure) of the corresponding descriptor, using an interrupt mechanism defined by the containing DMA Function's configuration registers. Software needs to clear the interrupt status by writing "1" to the Bit 31 (Interrupt Flag) of register at offset 20h.

◇ In DMA Engine (Function) Configuration registers for function 1 or 2, it defines various interrupt mechanisms such as INTx Interrupt message enabled by Bit-10 of command register at offset 04h (via configuration space), MSI/Multiple MSI enabled by Bit-16/Bit22:20 of MSI control register at offset 48h or MSI-X enabled by Bit-31 of MSI-X control register at offset B0h.

◇ TPH: Defined in bit-29. Software may configure a descriptor with a flag (setting TPH of CTRL field) to indicate that the posted memory writes issued by the DMA engine for this descriptor should include a set of TLP Processing Hints (TPH). The TPH will consist of setting the TH bit in each posted write's TLP header, and incorporating an 8-bit ST (7:0) steering tag data field that is found in the DMA descriptor. The steering tag in the TLP header is copied from ST value defined in Bit: 7~0 of 1st DW in descriptor.

8.3.3.4   ERR FIELD

This 5-bit field can encode into 32 errors at most. In descriptor level, the DMA might detect the following errors such as Data Poison (encoded as 12, which is corresponding to bit-12 in AER), Completion Time-Out (bit-14), Completer Abort (Bit-15), ECRC error (Bit-19) and Unsupported Request (Bit-20). If there are more than two errors (included) happening at the same time, it always reports the error defined with the least bit.

8.3.3.5   ST FIELD

It represents 8-bit steering tag. This 8-bit data is valid only when TPH bit set in control field.

8.3.3.6   CRC FIELD

Software may configure a descriptor with a flag to indicate that the DMA engine should compute a CRC-32 checksum of the data bytes (not including headers) that were read as part of the DMA transfer. The calculated CRC-32 will be written back to the descriptor on completion.

By setting CRC of CTRL field (bit-21 of the 1st DW), it enables DMA engine to compute a CRC-32 checksum over the raw data bytes of buffer pointed by the descriptor. It uses PCIe ECRC-32 polynomial and calculation is in a DW alignment. Upon the completion of descriptor processing, the final CRC-32 checksum result will be written back to the 8th DW of descriptor.

8.4   ERROR REPORTING AND HANDLING

The software managing a DMA function and associated channels must be able to define appropriate error handling behaviors for the DMA processing, including the handling of DMA memory read failures. To implement appropriate error handling for DMA:

8.4.1 ERROR REPORTING

Software will discover the Advanced Error Reporting (AER) capability in the configuration space of each DMA Function. Software will then enable AER, and configure the AERUCES, AERUCEM, AERUCESEV, AERCS, AERCEM, AERCC, AERHL, and AERTLP registers appropriately. The switch will update these registers and issue M_ERR messages as the DMA engine detects errors when processing a descriptor from the corresponding function. The switch will also rewrite the descriptor affected by an error with an error status field, indicating the corresponding PCIe error that caused the DMA to fail (e.g. DP, ECRC, CTO).

8.4.1.1   REPORTING VIA FUNCTION

In DMA Engine (Function) Configuration registers for function 1 or 2, it defines Advanced Error Reporting (AER) capability at byte offset 100h that followed by AERUCES, AERUCEM, AERUCESEV, AERCES, AERCEM, AERCC and AERHL registers from a byte offset 104h to 128h.

8.4.1.2   REPORTING VIA CHANNEL

When processing any descriptor in all of channels assigned to that DMA function, it will issue UCE_MSG If any of UCE is detected and also the corresponding UCE bit in AERUCEM is cleared. Meanwhile, the AERUCES would be copied to Channel UCES register defined in DMA interface register at offset 44h, so it will know which channel causing UCE. Furthermore, bit 25:24 of Channel UCES register will also indicate what type of DMA transaction running into Uncorrectable error. Bit-24 represents the detected error happening in fetching descriptor while Bit-25 shows that error detected in reading data into DMA buffer. The DMA engine will issue interrupt if UCE Interrupt Enable bit (bit 17 of DMA Control and Status 0) is turned on.

8.4.1.3   REPORTING VIA DESCRIPTOR

To continuously trace down from where the UCE is coming, the DMA engine will also write back the error status to the descriptor which is affected by an error with a 5-bit error status field (bit 12 ~ 7 of 1st DW in descriptor). A 5-bit error status field can represent any of the PCIe UEs defined in AERUCES (e.g. error field=12 in descriptor would mean DP because DP is the 12th bit of AERUCES). Once Multiple UEs happen simultaneously, the lowest bit position in AERUCES will be recorded. (e.g. if DP (Bit 12 in AERUCES) and Malformed TLP (Bit 18 in AERUCES) are detected, only the DP reported as error since it is a lowest bit)

8.4.2 ERROR LOGGING

The DMA Function will provide a default (or configurable) value for AERCAP + 18h AERCC.MHRC, and errors will be logged appropriately into AERHL and AERTLP as detected when processing a descriptor from the corresponding function. The default value for AERCC.MHRC is zero, so there is only one TLP header with error(s) will be logged into AERHL.

8.4.3 DATA INTEGRITY

The switch will implement ECRC checking and ECRC generation for TLPs passing through the DMA engine. As such, the DMA Function will set AERCC.ECC=1 and AEREGC=1 in the AER capability, DMA Reads will verify ECRC, and DMA Writes will generate ECRC.

In AERCC register of DMA function configuration space, it defines ECC (bit-7) and EGC (bit-5) as "1" so the system software can set ECE =1 (bit-8) and EGE = 1 (bit-6) to enable the switch to perform ECRC checking and ECRC generation for TLPs passing through the DMA engine.

8.4.4 ERROR HANDLING FOR UNCORRECTABLE ERROR DETECTED

The switch will provide software the channel status to determine whether a particular detected error will automatically stop the channel, or simply mark the descriptor as being in error, and continue processing the next descriptor. Once detecting uncorrectable error, the DMA will write back error status into the descriptor which is affected by error(s). Also, the switch will take the following steps for two scenarios.

8.4.4.1 ERROR IN DATA BUFFER

If the error occurs in the TLPs that are CPLDs for storing into DMA data buffer, the DMA activity drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data. The pointer will move to the next active descriptor and this would be treated like an H/W abort event. This channel is aborted and it is up to Software to restart DMA from the next descriptor or re-program the DMA control register to start from the base descriptor.

8.4.4.2 ERROR IN DESCRIPTOR

If the error occurs in the TLPs that are CPLDs for storing into Prefetch descriptor cache, the DMA activity not only drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data, but also dumps the following descriptors since they are damaged as well. So this channel is stopped and requires Software to reprogram interface registers for re-initialization before resuming DMA activity by setting DMA Start (Bit 0).

8.4.5 ERROR HANDLING FOR DMA READ

The switch will provide a register for the DMA function that software can use to determine whether an error on DMA Memory Read will cause the function and/or descriptor to report an error immediately (without writing), or will cause the function and/or descriptor to report an error only after writing to the DMA destination address a Poisoned (DP) Memory Write TLP for each corresponding Memory Read that failed.
If the UCE occurring in DMA read for CPLDs acquired from source address, the error report scheme (Bit-18 in DMA Control and Status Register 0) can be configured in two different modes.
◊   If Bit-18 is set, DMA reports UCE event after writing DP TLP to destination address. The DP TLP is generated for each corresponding memory read that failed.
◊   If Bit-18 is cleared, DMA reports UCE event immediately without writing DP TLP to destination address.

9   REGISTER DESCRIPTION

9.1   REGISTER TYPES

This chapter details the Packet Switch registers, including
- Bit names
- Description of register functions
- Type, refer to Table 9-1
- Whether the default value can be modified by EEPROM and/or I2C.
- Default value

Table 9-1 Register Types

REGISTER TYPE	DEFINITION
HwInt	Hardware Initialization
RO	Read Only
RW	Read / Write
RW1C	Read / Write 1 to Clear
RW1O	Read/Write 1 Only
RsvdP	RO and must return 0 when read.

9.2   REGISTER ACCESS

Each Switch Port implements a 4-KB Configuration Space which includes the lower 256 bytes PCI-compatible Configuration Space, and the upper 3840 bytes PCI Express Extended Configuration Space. There are several mechanisims can access the Configuration Space:

- PCI-compatible Configuration Mechanism
- PCI Express Enhanced Configuration Access Mechanism
- Device-specific Memory Mapped Configuration Mechanism
- I2C Slave Interface

9.2.1 PCI-COMPATIBLE CONFIGURATION MECHANISM

The PCI-compatible Configuration Mechanism provides standard access to the first 256 bytes of the PCI Express Configuration Space. The mechanism uses PCI Type 0 and Type 1 Configuration transactions to access the Packet Switch Configuration registers.

9.2.2 PCI EXPRESS ENHANCED CONFIGURATION ACCESS MECHANISM

The PCI Express Enhanced Configuration Access Mechanism is implemented on all PCI Express PCs. It provides a memory-mapped address space in the root complex, through which the root complex translates a memory access into one or more configuration requests. Device drivers normally use an application programming interface (API) provided by the Operating System (OS) to use this mechanism. The mechanism can access all Packet Switch registers.

9.2.3 DEVICE_SPECIFIC MEMORY MAPPED CONFIGURATION MECHANISM

The Device-Specific memory-Mapped Configuration Mechanism provides a method to access the configuration registers of all ports in a single 512KBmemory map. The registers of each port are contained within a 4-KB range.

To use this mechanism, BIOS/OS needs to set BAR 0 and BAR 1 registers of up port at boot time. After BAR 0 and BAR 1 are enumerated, Port 0 registers can be access with Memory Reads from and Writes to the first 4 KB, Port 1 registers can be accessed with Memory Reads from and Writes to the 2nd , and so forth.

Physical Location Index	Port Number	BAR 0/1 Offset
Port 0	0000_0000b	0_0000h
Port 1	0000_0001b	0_1000h
…	…	…
Port 7	0000_0111b	0_7000h
CDEP 1	1001_0000b	7_0000h
CQ Header Location	N/A	6_F000h

Note: "Port Number" is defined in link capabilities register (offset 74h) bit [31:24].

9.3 TRANSPARENT MODE CONFIGURATION REGISTERS

When the port of the Switch is set to operate at the transparent mode, it is represented by a logical PCI-to-PCI Bridge that implements type 1 configuration space header. The following table details the allocation of the register fields of the PCI 2.3 compatible type 1 configuration space header.

Other than the PCI 2.3 compatible configuration space header, the Switch also implements PCI express extended configuration space header, which includes advanced error reporting, virtual channel, and power budgeting capability registers. The following table details the allocation of the register fields of PCI express extended capability space header. The first extended capability always begins at offset 100h with a PCI Express Enhanced Capability header and the rest of capabilities are located at an offset greater than 0FFh relative to the beginning of PCI compatible configuration space.

7:0	SSID/SSVID Capabilities ID	RO	Read as 0Dh to indicate that this is SSID/SSVID capability register.	Yes	0Dh
15:8	Next Item Pointer	RO	Point to next PCI capability structure.	Yes	B0h for Up 00h for Down
31:16	Reserved	RsvdP	Not support.	No	0000h

9.3.61 SUBSYSTEM VENDOR ID REGISTER – OFFSET A8h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
15:0	SSVID	RO	It indicates the sub-system vendor id.	Yes	12D8h

9.3.62 SYSTEM ID REGISTER – OFFSET A8h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
31:16	SSID	RO	It indicates the sub-system device id.	Yes	C008h

9.3.63 MSI-X CAPATILITIES REGISTER – OFFSET B0h (Upstream Port Only)

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
7:0	MSI-X Capabilities ID	RO	Read as 11h to indicate that this is MSI-X capability register.	No	11h
15:8	Next Item Pointer	RO	Read as 00h. No other ECP registers.	Yes	00h
26:16	Table Size	RO	System software reads this field to determine the MSI-X Table Size N, which is encoded as N-1.	No	005h
29:27	Reserved	RsvdP	Not support,	No	000b
30	Function Mask	RW	If set, all of the vectors associated with the function are masked, regardless of their per-vector mask bit values. If clear, each vector's mask bit determines whether the vector is masked or not.	No/Yes	0
31	MSI-X Enable	RW	If set and the MSI Enable bit in the MSI Message Control register is clear, the function is permitted to use MSI-X to request service and is prohibited from using INTx interrupts (if implemented). If clear, the function is prohibited from using MSI-X to request service.	No/Yes	0

9.3.64 MSI-X TABLE OFFSET/TABLE BIR REGISTER – OFFSET B4h (Upstream Port Only)

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
2:0	Table BIR	RO	Read as 000b to indicate Base Address 0 register (offset 10h in Configuration Space) is used to map the function MSI-X Table into Memory space.	Yes	000b
31:3	Table Offset	RO	Used as an offset from the address contained by one of the function's Base Address registers to point to the base of the MSI-X Table.	Yes	0000_FE00h

9.3.65 MSI- X PBA OFFSET / PBA BIR REGISTER – OFFSET B8h (Upstream Port Only)

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
2:0	PBA BIR	RO	Read as 000b to indicate Base Address 0 register (offset 10h in Configuration Space) is used to map the function MSI-X PBA into Memory space.	Yes	000b
31:3	PBA Offset	RO	Used as an offset from the address contained by one of the function's Base Address registers to point to the base of the MSI-X PBA.	Yes	0000_FE10h

9.3.66 BAR 0 CONFIGURATION REGISTER – OFFSET E0h (Upstream Port Only)

19:16	Capability Version	RO	Read as 1h.	No	01h
31:20	Next Capability Offset	RO	Point to next PCI extended capability structure.	Yes	1A0h

9.3.77   PORT VC CAPABILITY REGISTER 1 – OFFSET 134h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/I2C	DEFAULT
2:0	Extended VC Count	RO	It indicates the number of extended Virtual Channels in addition to the default VC supported by the Switch.	No	000b
3	Reserved	RO	Not support.	No	0
6:4	Low Priority Extended VC Count	RO	It indicates the number of extended Virtual Channels in addition to the default VC belonging to the low-priority VC (LPVC) group.	No	000b
7	Reserved	RO	Not support.	No	0
9:8	Reference Clock	RO	It indicates the reference clock for Virtual Channels that support time-based WRR Port Arbitration. Defined encoding is 00b for 100 ns reference clock.	No	00b
11:10	Port Arbitration Table Entry Size	RO	Read as 10b to indicate the size of Port Arbitration table entry in the device is 4 bits.	No	10b
31:12	Reserved	RsvdP	Not support.	No	0000_0h

9.3.78   PORT VC CAPABILITY REGISTER 2 – OFFSET 138h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/I2C	DEFAULT
7:0	VC Arbitration Capability	RO	It indicates the types of VC Arbitration supported by the device for the LPVC group. This field is valid when LPVC is greater than 0. The Switch supports Hardware fixed arbitration scheme, e.g., Round Robin and Weight Round Robin arbitration with 32 phases in LPVC.	No	00h
23:8	Reserved	RsvdP	Not support.	No	0000h
31:24	VC Arbitration Table Offset	RO	It indicates the location of the VC Arbitration Table as an offset from the base address of the Virtual Channel Capability register in the unit of DQWD (16 bytes).	No	00h

9.3.79   PORT VC CONTROL REGISTER – OFFSET 13Ch

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/I2C	DEFAULT
0	Load VC Arbitration Table	WO	When set, the programmed VC Arbitration Table is applied to the hardware. This bit always returns 0b when read.	Yes	0

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
3:1	VC Arbitration Select	RW	This field is used to configure the VC Arbitration by selecting one of the supported VC Arbitration schemes. The valid values for the schemes supported by Switch are 0b and 1b. Other value than these written into this register will be treated as default.	No/Yes	000b
15:4	Reserved	RsvdP	Not support.	No	000h

9.3.80 PORT VC STATUS REGISTER – OFFSET 13Ch

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
16	VC Arbitration Table Status	RO	When set, it indicates that any entry of the VC Arbitration Table is written by software. This bit is cleared when hardware finishes loading values stored in the VC Arbitration Table after the bit of "Load VC Arbitration Table" is set.	No	0
31:17	Reserved	RsvdP	Not support.	No	0-0h

9.3.81 VC RESOURCE CAPABILITY REGISTER (0) – OFFSET 140h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
7:0	Port Arbitration Capability	RO	It indicates the types of Port Arbitration supported by the VC resource. The Switch supports Round Robin Hardware fixed arbitration scheme.	No	01h
13:8	Reserved	RsvdP	Not support.	No	00_0000h
14	Advanced Packet Switching	RO	When set, it indicates the VC resource only supports transaction optimized for Advanced Packet Switching (AS).	No	0
15	Reject Snoop Transactions	RsvdP	Not support.	No	0
22:16	Maximum Time Slots	RO	It indicates the maximum numbers of time slots (minus one) are allocated for Isochronous traffic.	No	3Fh
23	Reserved	RsvdP	Not support.	No	0
31:24	Port Arbitration Table Offset	RO	It indicates the location of the Port Arbitration Table (n) as an offset from the base address of the Virtual Channel Capability register in the unit of DQWD (16 bytes).	No	05h

9.3.82 VC RESOURCE CONTROL REGISTER (0) – OFFSET 144h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
7:0	TC/VC Map	RW	This field indicates the TCs that are mapped to the VC resource. Bit locations within this field correspond to TC values. When the bits in this field are set, it means that the corresponding TCs are mapped to the VC resource. Bit 0 of this filed is read-only and must be set to "1" for the VC0.	No/Yes	FFh
15:8	Reserved	RsvdP	Not support.	No	00h
16	Load Port Arbitration Table	RW	When set, the programmed Port Arbitration Table is applied to the hardware. This bit always returns 0b when read.	No/Yes	0
19:17	Port Arbitration Select	RW	This field is used to configure the Port Arbitration by selecting one of the supported Port Arbitration schemes. The permissible values for the schemes supported by Switch are 000b and 011b at VC0, other value than these written into this register will be treated as default.	No/Yes	000b
23:20	Reserved	RsvdP	Not support.	No	0h
26:24	VC ID	RO	This field assigns a VC ID to the VC resource.	No	000b
30:27	Reserved	RsvdP	Not support.	No	0h
31	VC Enable	RW	0b: it disables this Virtual Channel 1b: it enables this Virtual Channel	No/Yes	1

9.3.89 POWER BUDGETING DATA REGISTER – OFFSET 1B8h (Upstream Port Only)

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
7:0	Base Power	RO	It specifies the base power value in watts. This value represents the required power budget in the given operation condition.	Yes	04h if 13Ch.bit[0]=0 03h if 13Ch.bit[0]=1
9:8	Data Scale	RO	It specifies the scale to apply to the base power value.	Yes	00b
12:10	PM Sub State	RO	It specifies the power management sub state of the given operation condition. It is initialized to the default sub state.	Yes	000b
14:13	PM State	RO	It specifies the power management state of the given operation condition. It defaults to the D0 power state.	Yes	00b
17:15	Type	RO	It specifies the type of the given operation condition which is controlled by offset 13Ch[7:0]. It defaults to the Maximum power state.	Yes	7h if 13Ch.bit[0]=0 3h if 13Ch.bit[0]=1
20:18	Power Rail	RO	It specifies the power rail of the given operation condition.	Yes	010b
31:21	Reserved	RsvdP	Not support.	No	0-0h

9.3.90 POWER BUDGET CAPABILITY REGISTER – OFFSET 1BCh (Upstream Port Only)

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
16	Switch Output Singal Source	RW	When set, it will switch debug_mode GPIO[23:17;15:12;9:0] output signal source from internal debug_out to debug memory stored debug_out data.	Yes	0
17	Enable User-Defined Mode	RW	When set, it will select internal debug_out port_sel/mode_sel to bit[5:0]/bit[12:8] port_sel/mode_sel value.	Yes	0
18	PORT_GOOD Setting	RW	When set, it will switch PORT_GOOD_L[7:4;1:0] output from original link status to internal error status.	Yes	0
31:19	Reserved	RsvdP	Not support.	No	0-0h

9.3.267 WAVEFORM READ EVENT RESET REGISTER – OFFSET 748h (Port 0 Only)

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
0	Back to waveform by CFG/I2C	WO	When set, the read point will back to the header of the waveform. Reading returns 0 always.	Yes	0
31:1	Reserved	RsvdP	Not support.	No	0-0h

9.3.268 DUMP MEMORY TO GPIO RATE CONTROL REGISTER – OFFSET 74Ch (Port 0 Only)

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
3:0	Dump Waveform to LA Sample Rate Setting	RW	Used to set the debug memory 32 bits data output to GPIO[23:17;15:12;9:0] rate. 0h: output to GPIO[23:17;15:12;9:0] as 500MHz clock rate 1h: output to GPIO[23:17;15:12;9:0] as 250HHz clock rate 2h: output to GPIO[23:17;15:12;9:0] as 125MHz clock rate …	Yes	0h
31:4	Reserved	RsvdP	Not support.	No	0-0h

9.3.269 DUMP WAVEFORM START REGISTER – OFFSET 750h (Port 0 Only)

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
0	Dump Waveform Start	RW	When set, start to dump waveform to LA.	Yes	0
31:1	Reserved	RsvdP	Not support.	No	0-0h

9.3.270 FREE RUN BUTTON REGISTER – OFFSET 754h (Port 0 Only)

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
0	Free Run Button	RW	When set, debug memory will store pre-defined internal debug_out[23:17;15:12;9:0] data, and output to GPIO[23:17;15:12;9:0] automatically.	Yes	0
31:1	Reserved	RsvdP	Not support.	No	0-0h

9.4   CDLEP CONFIGURATION REGISTERS

When the port of the Switch is set to operate at the cross-domain end point mode, it is represented by an Other Bridge that implementstype 0configuration space header. The following table details the allocation of the register fields of the PCI 2.3 compatible type 0 configuration space header.

Please be aware of those registers marked as port 0 only, which are defined for management purpose.

Other than the PCI 2.3 compatible configuration space header, the Switch also implements PCI express extended configuration space header, which includes advanced error reporting, virtual channel, and power budgeting capability registers. The following table details the allocation of the register fields of PCI express extended capability space header. The first extended capability always begins at offset 100h with a PCI Express Enhanced Capability header and the rest of capabilities are located at an offset greater than 0FFh relative to the beginning of PCI compatible configuration space.

9.4.8 PRIMARY LATENCY TIMER REGISTER – OFFSET 0Ch

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
15:8	Primary Latency Timer	RsvdP	Not support.	No	00h

9.4.9 HEADER TYPE REGISTER – OFFSET 0Ch

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
23:16	Header Type	RO	Read as 00h to indicate that the register layout conforms to Type 0 Configuration header for CDLEP port.	No	00h

9.4.10   BAR 0 REGISTER – OFFSET 10h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
0	Memory Space Indicator	RO	Reset to 0b to indicate Memory Base address.	No	0
2:1	64-bit Addressing	RO	00b: 32-bit addressing 10b: 64-bit addressing Others: Reserved	No	00b
3	Prefetchable	RO	0b: Non-prefetchable 1b: Prefetchable	No	0
18:4	Reserved	RsvdP	Not support.	No	0h
31:19	Base Address 0 [31:19]	RW	Use this Memory base address to map the packet switch registers.	No/Yes	0-0h

9.4.11   BAR 1 REGISTER – OFFSET 14h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
31:0	Reserved	RO	When the Base Address 0 register is not 64-bit addressing (offset 10h[2:1] is not 10b).	No	0000_0000h
	Base Address 0 [63:32]	RW	When the Base Address 0 register is 64-bit addressing. Base Address 1 is used to provide the upper 32 Address bits when offset 10h[2:1] is set to 10b.	No/Yes	

9.4.12   BAR 2 REGISTER – OFFSET 18h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
0	Memory Space Indicator	RO	Reset to 0b to indicate it is a Memory BAR.	No	0
2:1	Memory Map Type	RO	00b: support 32-bit Memory Space 10b: support 64-bit Memory Space When 64-bit memory space is supported, the assigned memory address has to be larger than 4GB.	No	00b
3	Prefetchable	RO	0b: Non-prefetchable 1b: Prefetchable	No	0
19:4	Reserved	RsvdP	Not support.	No	0-0h
31:20	Base Address 2 [31:20]	RW	Base Address 2.	No/Yes	000h

9.4.16   SSVID REGISTER – OFFSET 2Ch

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
15:0	SSVID	RO	Identifies the sub-system vendor id.	Yes	12D8h

9.4.17   SSID REGISTER – OFFSET 2Ch

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
31:16	SSID	RO	Identifies the sub-system device id.	Yes	C232h

9.4.18   CAPABILITY POINTER REGISTER – OFFSET 34h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
7:0	Capability Pointer	RO	Point to first PCI capability structure.	Yes	40h

9.4.19   INTERRUPT LINE REGISTER – OFFSET 3Ch

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
7:0	Interrupt Line	RW	The interrupt line register communicates interrupt line routing information.	No/Yes	00h

9.4.20   INTERRUPT PIN REGISTER – OFFSET 3Ch

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
15:8	Interrupt Pin	RO	The Switch implements INTA virtual wire interrupt signal.	Yes/No	01h

9.4.21   POWER MANAGEMENT CAPABILITIES REGISTER – OFFSET 40h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
7:0	Enhanced Capabilities ID	RO	Read as 01h to indicate that this is power management capability register.	Yes	01h
15:8	Next Item Pointer	RO	Point to next PCI capability structure.	Yes	48h
18:16	Power Management Revision	RO	Read as 011b to indicate the device is compliant to Revision 1.2 of *PCI Power Management Interface Specifications.*	No	011b
19	PME# Clock	RO	Does not apply to PCI Express. Must be hardwired to 0.	No	0
20	Reserved	RsvdP	Not support.	No	0
21	Device specific Initialization	RO	Read as 0b to indicate Switch does not have device specific initialization requirements.	Yes	0
24:22	AUX Current	RO	Reset to 000b.	Yes	000b
25	D1 Power State Support	RO	Read as 0b to indicate Switch does Not support the D1 power management state.	Yes	0
26	D2 Power State Support	RO	Read as 0b to indicate Switch does Not support the D2 power management state.	Yes	0
31:27	PME# Support	RO	Read as 19h to indicate Switch supports the forwarding of PME# message in D0, D3 and D4 states.	Yes	C8h

9.4.22   POWER MANAGEMENT DATA REGISTER – OFFSET 44h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
1:0	Power State	RW	Indicates the current power state of the Switch. Writing a value of D0 when the previous state was D3 cause a hot reset without asserting DWNRST_L. 00b: D0 state 01b: D1 state 10b: D2 state 11b: D3 hot state	No/Yes	00b
2	Reserved	RsvdP	Not support.	No	0
3	No_Soft_Reset	RO	When set, this bit indicates that device transitioning from D3hot to D0 does not perform an internal reset. When clear, an internal reset is performed when power state transits from D3hot to D0.	Yes	1
7:4	Reserved	RsvdP	Not support.	No	0h
8	PME# Enable	RW	When asserted, the Switch will generate the PME# message.	No/Yes	0
12:9	Data Select	RW	Select data registers. RW if offset 4C4h[9]=1 and RO if offset 4C4h[9]=0.	No/Yes	0h
14:13	Data Scale	RO	Reset to 00b.	No/Yes	00b
15	PME Status	RW1C	Read as 0b as the PME# message is not implemented.	No/Yes	0

31:24	Data Register	RO	Data Register.	Yes	00h

9.4.25 MSI CAPABILITIES REGISTER – OFFSET 48h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
7:0	Enhanced Capabilities ID	RO	Read as 05h to indicate that this is message signal interrupt capability register.	No	05h
15:8	Next Item Pointer	RO	Point to next PCI capability structure.	Yes	68h
16	MSI Enable	RW	0b: The function is prohibited from using MSI to request service 1b: The function is permitted to use MSI to request service and is prohibited from using its INTx # pin	No/Yes	0
19:17	Multiple Message Capable	RO	Indicate the number of requested vectors.	Yes	011b
22:20	Multiple Message Enable	RW	Software writes to this field to indicate the number of allocated vectors (equal to or less than the number of requested vectors.)	No/Yes	000b
23	64-bit address capable	RO	0b: The function is not capable of generating a 64-bit message address 1b: The function is capable of generating a 64-bit message address	Yes	1b
24	Pre-vector Masking Capable	RO	1b: the function supports MSI pre-vector masking. 0b: the function does Not support MSI pre-vector masking.	Yes	1b
31:25	Reserved	RO	Not support.	No	00h

9.4.26 MESSAGE ADDRESS REGISTER – OFFSET 4Ch

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
1:0	Reserved	RsvdP	Not support.	No	00b
31:2	Message Address	RW	If the message enable bit is set, the contents of this register specify the DWORD aligned address for MSI memory write transaction.	No/Yes	0-0h

9.4.27 MESSAGE UPPER ADDRESS REGISTER – OFFSET 50h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
31:0	Message Upper Address	RW	This register is only effective if the device supports a 64-bit message address is set.	No/Yes	0000_0000h

9.4.28 MESSAGE DATA REGISTER – OFFSET 54h

9.4.31   PCI EXPRESS CAPABILITIES REGISTER – OFFSET 68h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/I2C	DEFAULT
7:0	Enhanced Capabilities ID	RO	Read as 10h to indicate that this is PCI express enhanced capability register.	No	10h
15:8	Next Item Pointer	RO	Point to next PCI capability structure.	Yes	A4h
19:16	Capability Version	RO	Read as 2h to indicate the device is compliant to Revision .2.0 of *PCI Express Base Specifications.*	Yes	2h
23:20	Device/Port Type	RO	Indicates the type of PCI Express logical device.	Yes	00h
24	Slot Implemented	RsvdP	Not support.	No	0
29:25	Interrupt Message Number	RO	No MSI messages are generated in the transparent mode.	No	00_000b
31:30	Reserved	RsvdP	Not support.	No	00b

9.4.32   DEVICE CAPABILITIES REGISTER – OFFSET 6Ch

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/I2C	DEFAULT
2:0	Max_Payload_Size Supported	RO	Indicates the maximum payload size that the device can support for TLPs. Each port of the Switch supports 512 bytes max payload size.	Yes/No	010b
4:3	Phantom Functions Supported	RO	Indicates the support for use of unclaimed function numbers as Phantom functions. Read as 00b, since the Switch does not act as a requester.	No	00b
5	Extended Tag Field Supported	RO	Indicates the maximum supported size of Tag field as a Requester. Read as 0, since the Switch does not act as a requester.	No	0
8:6	Reserved	RsvdP	Not support.	No	111b
11:9	Reserved	RsvdP	Not support.	No	111b

15	Role_Based Error Reporting	RO	When set, indicates that the device implements the functionality originally defined in the Error Reporting ECN.	Yes	1
17:16	Reserved	RsvdP	Not support.	No	00b
25:18	Captured Slot Power Limit Value	RO	In combination with the Slot Power Limit Scale value, specifies the upper limit on power supplied by slot.\n\nThis value is set by the Set_Slot_Power_Limit message or hardwired to 00h.	No	00h
27:26	Captured Slot Power Limit Scale	RO	Specifies the scale used for the Slot Power Limit Value.\n\nThis value is set by the Set_Slot_Power_Limit message or hardwired to 00b.	No	00b
31:28	Reserved	RsvdP	Not support.	No	0h

9.4.33   DEVICE CONTROL REGISTER – OFFSET 70h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
0	Correctable Error Reporting Enable	RW	0b: Disable Correctable Error Reporting\n1b: Enable Correctable Error Reporting	No/Yes	0
1	Non-Fatal Error Reporting Enable	RW	0b: Disable Non-Fatal Error Reporting\n1b: Enable Non-Fatal Error Reporting	No/Yes	0
2	Fatal Error Reporting Enable	RW	0b: Disable Fatal Error Reporting\n1b: Enable Fatal Error Reporting	No/Yes	0
3	Unsupported Request Reporting Enable	RW	0b: Disable Unsupported Request Reporting\n1b: Enable Unsupported Request Reporting	No/Yes	0
4	Enable Relaxed Ordering	RsvdP	When set, it permits the device to set the Relaxed Ordering bit in the attribute field of transaction. Since the Switch can not either act as a requester or alter the content of packet it forwards, this bit always returns '0' when read.	No	0
7:5	Max_Payload_Size	RW	This field sets maximum TLP payload size for the device. Permissible values that can be programmed are indicated by the Max_Payload_Size Supported in the Device Capabilities register. Any value exceeding the Max_Payload_Size Supported written to this register results into clamping to the Max_Payload_Size Supported value.	No/Yes	000b
8	Extended Tag Field Enable	RW	0b: Disable Extended Tag Field\n1b: Enable Extended Tag Field	No/Yes	0
9	Phantom Function Enable	RsvdP	Does not apply to PCI Express Switch. Returns '0' when read.	No	0
10	Auxiliary (AUX) Power PM Enable	RO	When set, indicates that a device is enabled to draw AUX power independent of PME AUX power.	No	0
11	Enable No Snoop	RsvdP	When set, it permits to set the No Snoop bit in the attribute field of transaction. Since the Switch can not either act as a requester or alter the content of packet it forwards, this bit always returns '0' when read.	No	0
14:12	Max_Read_ Request_Size	RsvdP	This field sets the maximum Read Request size for the device as a Requester. Since the Switch does not generate read request by itself, these bits are hardwired to 000b.	No	000b
15	Reserved	RsvdP	Not support.	No	0

9.4.34   DEVICE STATUS REGISTER – OFFSET 70h

9.4.35 LINK CAPABILITIES REGISTER – OFFSET 74h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
3:0	Maximum Link Speed	RO	Indicates the maximum speed of the Express link is 8Gb/s, 5Gb/s and 2.5 Gb/s. 0001b: 2.5 Gb/s 0001b: 5.0 Gb/s 0011b: 8.0 Gb/s Others: Reserved	Yes	3h
9:4	Maximum Link Width	RO	Indicates the maximum width of the given PCIe Link. 00_0001b: x1 lane width 00_0010b: x2 lane width	Yes	Set by PORTCFG [2:0]
11:10	Active State Power Management (ASPM) Support	RO	Indicates the level of ASPM supported on the given PCIe Link. Each port of Switch supports L0s and L1 entry. This switch does not support ASPM function. Please set 00b by eeprom.	Yes	10b
14:12	L0s Exit Latency	RO	Indicates the L0s exit latency for the given PCIe Link. The length of time this port requires to complete transition from L0s to L0 is in the range of 256ns to less than 512ns.	Yes	011b
17:15	L1 Exit Latency	RO	Indicates the L1 exit latency for the given PCIe Link. The length of time this port requires to complete transition from L1 to L0 is less than 1us.	Yes	000b
18	Clock Power Management	RO	Indicates that component tolerates the removal of any reference clock via CLKREQ#.	Yes	1
19	Surprise Down Capability Enable	RsvdP	Not support.	No	0
20	Data Link Layer Active Reporting Capable	RO	This bit must be set to 1b if the component supports the optional capability of reporting the DL_Active state of the Data Link Control and Management State Machine.	Yes	0
21	Link BW Notify Cap.	RsvdP	Not support	No	0
22	Reserved	RsvdP	Not support.	No	1
23	Reserved	RsvdP	Not support.	No	0
31:24	Port Number	RO	Indicates the PCIe Port Number for the given PCIe Link.	Yes	90h

9.4.76 VC RESOURCE CAPABILITY REGISTER (0) – OFFSET 140h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
7:0	Port Arbitration Capability	RO	It indicates the types of Port Arbitration supported by the VC resource. The Switch supports Round Robin Hardware fixed arbitration scheme.	No	01h
13:8	Reserved	RsvdP	Not support.	No	00_0000h
14	Advanced Packet Switching	RO	When set, it indicates the VC resource only supports transaction optimized for Advanced Packet Switching (AS).	No	0
15	Reject Snoop Transactions	RsvdP	Not support.	No	0
22:16	Maximum Time Slots	RO	It indicates the maximum numbers of time slots (minus one) are allocated for Isochronous traffic.	No	3Fh
23	Reserved	RsvdP	Not support.	No	0
31:24	Port Arbitration Table Offset	RO	It indicates the location of the Port Arbitration Table (n) as an offset from the base address of the Virtual Channel Capability register in the unit of DQWD (16 bytes).	No	05h

9.4.77 VC RESOURCE CONTROL REGISTER (0)– OFFSET 144h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
7:0	TC/VC Map	RW	This field indicates the TCs that are mapped to the VC resource. Bit locations within this field correspond to TC values. When the bits in this field are set, it means that the corresponding TCs are mapped to the VC resource. Bit 0 of this filed is read-only and must be set to "1" for the VC0.	No/Yes	FFh
15:8	Reserved	RsvdP	Not support.	No	00h
16	Load Port Arbitration Table	RW	When set, the programmed Port Arbitration Table is applied to the hardware. This bit always returns 0b when read.	No/Yes	0
19:17	Port Arbitration Select	RW	This field is used to configure the Port Arbitration by selecting one of the supported Port Arbitration schemes. The permissible values for the schemes supported by Switch are 000b and 011b at VC0, other value than these written into this register will be treated as default.	No/Yes	000b
23:20	Reserved	RsvdP	Not support.	No	0h

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
31:0	GPIO Interrupt Polarity	RW	Controls whether GPIO Interrupt input is Active-Low or Active-High for the corresponding GPIOx signal. Bit[31:0] correspond to GPIO[31:0], respectively. 0b: GPIO Interrupt input is Active-Low 1b: GPIO Interrupt input is Active-High For 3G606, bit[31:24;16;11:10] are reserved	Yes	0000_0000h

9.4.108 GPIO 0-31 INTERRUPT STATUS REGISTER – OFFSET 33Ch (Port 0 Only)

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
31:0	GPIO Interrupt Status	RO	Indicates whether GPIO interrupt are inactive or active for the corresponding GPIOx signal. Bit[31:0] correspond to GPIO[31:0] respectively. 0b: GPIO interrupt is inactive 1b: GPIO interrupt is active For 3G606, bit[31:24;16;11:10] are reserved	No	0000_0000h

9.4.109 GPIO 0-31 INTERRUPT MASK REGISTER – OFFSET 340h (Port 0 Only)

BIT	FUNCTION	TYPE	DESCRIPTION	EEPROM/ I2C	DEFAULT
31:0	GPIO Interrupt Mask	RW	Indicates whether GPIO interrupts are masked or not masked for the corresponding GPIOx signal. Bit[31:0] correspond to GPIO[31:0], respectively. 0b: GPIO interrupt is unmasked 1b: GPIO interrupt is masked For 3G606, bit[31:24;16;11:10] are reserved	Yes	0000_0000h

9.4.252 REQ ID/DOMAIN LUT 0 – 15– OFFSET 924h to 960h

These 16 32-bit registers construct a Requester ID (RID) look-up table storing the RID of TLP issued from Remote host, which connected to the CDLEP port directly. The table content can be either built by hardware automatically or written by software of management CPU. There arecontrol signals defined in the 14th and 15th bits of Device

9.4.275 Source ID LUT 0 – 7 – OFFSET A80h to A9Ch

These 8 32-bit registers construct a Source ID look-up table storing the ID pointed to the switch where the requester is located at. Also, there are two bits of each entry to indicate if the requester is an embedded DMA function. The table content is programmed by management CPU. These 8 entries identified by index numbers (0 ~ 7) represent the distinct Source ID and the associated DMA attributes.

9.5   CDVEP CONFIGURATION REGISTERS

When the port of the Switch is set to operate at cross-domain end point mode, it is represented by an Other Bridge that implements type 0 configuration space header. The following table details the allocation of the register fields of the PCI 2.3 compatible type 1 configuration space header.

Other than the PCI 2.3 compatible configuration space header, the Switch also implements PCI express extended configuration space header, which includes advanced error reporting, virtual channel, and power budgeting capability registers. The following table details the allocation of the register fields of PCI express extended capability space header. The first extended capability always begins at offset 100h with a PCI Express Enhanced Capability header and the rest of capabilities are located at an offset greater than 0FFh relative to the beginning of PCI compatible configuration space.

These 16 32-bit registers construct a Requester ID (RID) look-up table storing the RID of TLP issued from Main Host, which connected to the upstream port directly. The table content can be either built by hardware automatically or written by software of management CPU. There are control signals defined in the 14th and 15th bits of Device Configuration 2 Register at offset 50Ch of Port 0 to decide RID LUT build-up mechanism for CDVEP P0 and CDLEP P4 respectively.

Other than the PCI 2.3 compatible configuration space header, the Switch also implements PCI express extended configuration space header, which includes advanced error reporting, virtual channel, and power budgeting capability registers. The following table details the allocation of the register fields of PCI express extended capability space header. The first extended capability always begins at offset 100h with a PCI Express Enhanced Capability header and the rest of capabilities are located at an offset greater than 0FFh relative to the beginning of PCI compatible configuration space.

9.7   DMA ENGINE INTERFACE REGISTERS

To enable DMA function, the packet switch defines a set of interface registers for software to control the DMA engine and monitor the status of DMA transfer. There are two DMA engines (DMA_0 and DMA_1) in this Switch to face either one common or two different CPU domains respectively, so it defines an independent interface for software to access its own registers in its own CPU domain. The interface registers contain per-channel DMA ontrol and status registers, descriptor ownership registers, descriptor pointer registersand property registers (such as max payload size, max read request size and bus number of CDEP port etc.) for cross-domain DMA transfer.

The interface registers are mapped to multiple 256-byte register blocks in memory mode and each 256-byte register block represents one channel. The register blocks can be accessed by the DMA Memory Base Address, which is obtained by DMA Base Address Register 0 (Func1, CFG offset 10h or Func2, CFG offset 10h based upon different DMA mode selection, and please note that each DMA engine is viewed as a PCIe function by enumeration).

Table 9-12 DMA Base Address in Memory Mode when DMA channels pertaining to the same host domain

DMA Engine	DMA Memory Base Address

9.7.1 DMA CONTROL AND STATUS REGISTER 0 – OFFSET 00h

BIT	FUNCTION	TYPE	DESCRIPTION	DEFAULT
0	No Snooping Mode	RW	Configuration of No Snooping. 0b: Disable no snooping 1b: Enable no snooping	0
1	Address Format	RW	Indicate the addressing system a DMA operation is riding on. 0b: 32-bit addressing system 1b: 64-bit addressing system	0
7:2	Reserved	RsvdP	Not support.	0000_00b
8	EOT Valid	RW	When set, the EOT bit in descriptor is valid under the condition of DMA channels. EOT bit will be updated from 0 to 1 by the switch once the data transfer indicated in that descriptor is ended.	0
16:9	Reserved	RsvP	Not support.	00h
17	UCE Interrupt Enable	RW	When set, Interrupt is issued when detecting Uncorrectable Error	0
18	Error Report Scheme	RW	When clear, DMA reports UCE event without writing DP TLP to destination address. When set, DMA reports UCE event after writing DP TLP to destination address	0
27:19	Reserved	RsvP	Not support.	0-0b
31:28	Channel ID	RO	Indicate the channel ID is used by which channel of DMA.	0h

9.7.2 DESCRIPTOR OWNERSHIP REGISTER 0 – OFFSET 04h

BIT	FUNCTION	TYPE	DESCRIPTION	DEFAULT
31:0	Descriptor Ownership 0	RW	Indicate the ownership of descriptor 0. That means the owner can access the buffer pointed by the address field of descriptor 0. 1b: the DMA channel owns the descriptor 0 0b: the DMA driver owns the descriptor 0 After the buffer prepared by DMA driver, it will write "1" to the corresponding descriptor ownership bit. After the descriptor is done, the DMA channel will clear the corresponding bit to "0".	0000_000h

9.7.3 DESCRIPTOR OWNERSHIP REGISTER1 – OFFSET 08h

BIT	FUNCTION	TYPE	DESCRIPTION	DEFAULT
31:0	Descriptor Ownership 1	RW	Indicate the ownership of descriptor. That means the owner can access the buffer pointed by the address field of descriptor 1. 1b: the DMA channel owns the descriptor 1 0b: the DMA driver owns the descriptor 1 After the buffer prepared by DMA driver, it will write "1" to the corresponding descriptor ownership bit. After the descriptor is done, the DMA channel will clear the corresponding bit to "0".	0000_000h

9.7.5 CHANNELDESCRIPTOR RING BASE POINTER (HIGH 32-bit) REGISTER – OFFSET 10h

BIT	FUNCTION	TYPE	DESCRIPTION	DEFAULT
31:0	Descriptor Ring Base Pointer (High 32-bit)	RW	Upper 32-bit of Base Pointer referring to the 1st entry of descriptor ring if 64-bit addressing system is used. It tells DMA channel where the descriptor is starting at.	0000_0000h

9.7.6 CHANNEL DESCRIPTOR CURRENT POINTER REGISTER – OFFSET 14h

BIT	FUNCTION	TYPE	DESCRIPTION	DEFAULT
11:0	Descriptor Current Pointer (Offset from Base Pointer)	RO	Indicating the current pointer (Offset from Base Pointer) referring to the descriptor that is under processing by DMA Engine in terms of index. A maximum of 4096 pointers are allowed.	000h
31:12	Reserved	RsvdP	Not support.	00000h

9.7.7 CHANNEL TRANSFER COUNT STATUS OF CURRENT DESCRIPTOR POINTER REGISTER – OFFSET 18h

BIT	FUNCTION	TYPE	DESCRIPTION	DEFAULT
23:0	Transfer Count Status	RO	Indicating how many byte counts have been not transferred for the current descriptor pointer.	00_0000h

9.7.8 CHANNEL GAP TIME CONTROL REGISTER – OFFSET 1Ch

BIT	FUNCTION	TYPE	DESCRIPTION	DEFAULT
15:0	Write Data Gap Time Control	RW	Control the gap time between DMA writes. It is represented by 16 bits in a unit of 4ns	0000h
31:16	Fetch Data Gap Time Control	RW	Control the gap time between DMA reads. It is represented by 16 bits in a unit of 4ns	0000h

9.7.9 DMA CONTROL AND STATUS REGISTER 1 – OFFSET 20h

BIT	FUNCTION	TYPE	DESCRIPTION	DEFAULT
0	DMA Start	RW1O	Start DMA operation. 1b: the DMA operation starts to fetch and process the descriptors except the DMA stop or abort status is on. 0b: the current pointer will be moved to the descriptor ring base pointer or next descriptor pointer and stop the DMA operation. This bit can only be written with "1" and will not take effect if written with "0". Only when DMA operation is stopped or aborted, this bit will be automatically cleaned to "0".	0
1	DMA Pause Control	RW	Pause DMA Operation.When set, the DMA operation is paused to the next active descriptor after completing the processing on current descriptor. It means that no more descriptors are processed and prefetched until the "Paused" condition is lifted. For Host-to-Host DMA operation, the remote-site has to pause its DMA operation at first and ensure the pause done status has been asserted. After that, the local-site is just allowed to pause DMA operation. If pause interrupt is enabled and pause control is also enabled, the interruptflagis asserted until cleared by software.	0

BIT	FUNCTION	TYPE	DESCRIPTION	DEFAULT
2	DMA Abort Control	RW	Abort DMA Operation. When set, the DMA operation drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data. The pointer will move to the next active descriptor. No more descriptors are processed and prefetched until the "Aborted" condition is lifted. All receiving data will be discarded if DMA abort asserted. Removing abort condition can only use DMA start control For Host-to-Host DMA operation, the remote-site has to abort its DMA operation at first and ensure the abort done status has been asserted. After that, the local-site is just allowed to abort DMA operation. If abort interrupt is enabled and abort control is also enabled, the interruptflagis asserted until cleared by software.	0
3	DMA Pause Interrupt Enable	RW	When set, Interrupt is issued when DMA operation is paused.	0
4	Reserved	RsvdP	Not support.	0
5	DMA Stop Interrupt Enable	RW	When set, Interrupt is issued when DMA operation is stopped..	0
6	DMA Abort Interrupt Enable	RW	When set, Interrupt is issued when DMA operation is aborted.	0
7	DMA Stop Control	RW1C	Stop DMA Operation. When set, the DMA operation drops the current active descriptor by flushing out all outstanding read commands and discarding all received completion data. The channel interface registers are all cleaned to default state except Interrupt flag bit if DMA stop enable is set earlier. No more descriptors are processed and prefetched. All receiving data will be discarded if DMA stop asserted. Removing stop condition can only use DMA start control For Host-to-Host DMA operation, the remote-site has to stop its DMA operation at first and ensure the stop done status has been asserted. After that, the local-site is just allowed to stop DMA operation. If stop interrupt is enabled and stop control is also enabled, the interrupt flag is asserted until cleaned by software	0
8	Ownership Flush	RW	Clear ownership register when DMA operation is stopped.	0
15:9	Reserved	RsvdP	Not support.	00h
16	DMA Pause Done Status	RO	Indicates the DMA operation is in "Paused" condition. Removing pause done status can use DMA Pause control.	0
17	DMA Abort Done Status	RO	Indicates the DMA operation is in "Aborted" condition. Removing abort done status can only use DMA start control.	0
18	DMA Stop Done Status	RO	Indicates the DMA operation is in "Stopped" condition. Removing Stop done status can only use DMA start control.	1
30:19	Reserved	RsvdP	Not support.	000h
31	Interrupt Flag	RW1C	Indicates the interrupt asserted.	0

10 POWER SEQUENCE

As long as PERST# is asserted, all PCI Express functions are held in reset. The main supplies ramp up to their specified levels (0.95V/1.8V). Sometime during this stabilization time, the REFCLK starts and stabilizes. After elapsing some time (i.e. 100 us) for the power and clock to become stable, PERST# is deasserted high and the PCI Express functions can start up.

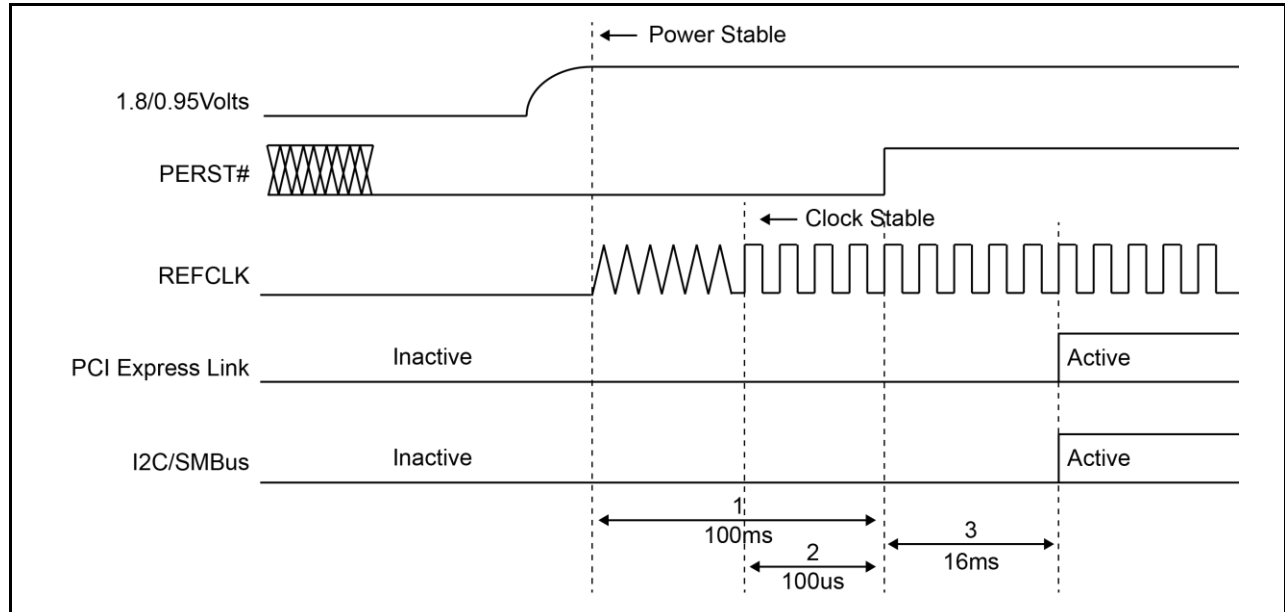

Figure 10-1 Initial Power-Up Sequence

11 IEEE 1149.1 COMPATIBLE JTAG CONTROLLER

An IEEE 1149.1 compatible Test Access Port (TAP) controller and associated TAP pins are provided to support boundary scan in PI7C9X3G606GP for board-level continuity test and diagnostics. The TAP pins assigned are TCK, TDI, TDO, TMS and TRST_L. All digital input, output, input/output pins except TAP pins and SERDES pins are tested.

11.1 INSTRUCTION REGISTER

The IEEE 1149.1 Test Logic consists of a TAP controller, an instruction register, and a group of test data registers including Bypass and Boundary Scan registers. The TAP controller is a synchronous 16-state machine driven by the Test Clock (TCK) and the Test Mode Select (TMS) pins. An independent power on reset circuit is provided to ensure the machine is in TEST_LOGIC_RESET state at power-up.

PI7C9X3G606GP implements a 5-bit Instruction register to control the operation of the JTAG logic. The defined instruction codes are shown in the following table. Those bit combinations that are not listed are equivalent to the BYPASS (1111) instruction.

Table 11-1 Instruction Register Codes

Instruction	Operation Code (binary)	Register Selected	Operation
EXTEST	0000	Boundary Scan	Drives / receives off-chip test data
SAMPLE	0010	Boundary Scan	Samples inputs
EXTEST_PULSE	0100	Boundary Scan	Drives/receives off-chip test data for TX/RX pins
EXTEST_TRAIN	0101	Boundary Scan	Drives/receives off-chip test data for TX/RX pins
SCAN_TEST	1010	Internal	Private instruction
IDCODE	0001	Device ID	Accesses the Device ID register, to read manufacturer ID, part number, and version number
RX_LEVEL	1011	Internal	Private instruction
NOC_BIST	0111	Internal	Private instruction
MBIST	1101	Internal	Private instruction
BYPASS	1111	Bypass	Selected Bypass Register

11.2 BYPASS REGISTER

The required bypass register (one-bit shift register) provides the shortest path between TDI and TDO when a bypass instruction is in effect. This allows rapid movement of test data to and from other components on the board. This path can be selected when no test operation is being performed on the PI7C9X3G606GP.

11.3 DEVICE ID REGISTER

This register identifies Diodes as the manufacturer of the device and details the part number and revision number for the device.

Table 11-2 JTAG Device ID Register

Bit	Type	Value	Description
31-28	RO	0001	Version number
27-12	RO	0001011000010110	Last 4 digits (hex) of the die part number
11-1	RO	01000111111	Diodes identifier assigned by JEDEC
0	RO	1	Fixed bit equal to 1'b1

11.4 BOUNDARY SCAN REGISTER

The boundary scan register has a set of serial shift-register cells. A chain of boundary scan cells is formed by connected the internal signal of the PI7C9X3G606GP package pins. The VDD, VSS, and JTAG pins are not in the boundary scan chain. The input to the shift register is TDI and the output from the shift register is TDO. There are 4 different types of boundary scan cells, based on the function of each signal pin.

The boundary scan register cells are dedicated logic and do not have any system function. Data may be loaded into the boundary scan register master cells from the device input pins and output pin-drivers in parallel by the mandatory SAMPLE and EXTEST instructions. Parallel loading takes place on the rising edge of TCK.

12 ELECTRICAL AND TIMING SPECIFICATIONS

12.1 ABSOLUTE MAXIMUM RATINGS

Table 12-1 Absolute Maximum Ratings

(Above which the useful life may be impaired. For user guidelines, not tested.)

Item	Absolute Max. Rating
Storage Temperature	-65'C to 150'C
Junction Temperature, Tj	125ºC
Digital core and analog supply voltage to ground potential (VDDC and AVDD)	VDDC +10%
Digital I/O and analog high supply voltage to ground potential (VDDR and AVDDH)	VDDR + 10%
DC input voltage for Digital I/O signals	2.75V
ESD Rating Human Body Model (JEDEC Class 2) Charge Device Model (JEDEC Class 3)	 HBM 2KV CDM 500V

Note:

Stresses greater than those listed under MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect reliability.

12.2 DC ELECTRICAL CHARACTERISTICS

Note:

1. The min. value for PERST_L Slew Rate is 50 mV/ns, which translates to the requirement that the time for PERST_L from 0V to 2.5V should be less than 50 ns.
2. Peak to peak AC noise < 5% of DC level.
3. Peak to peak AC noise < 3% of DC level.

12.3 PCIE REFERENCE CLOCK REQUIREMENTS

Table 12-1 specifies the voltage/timing requirements and operating characteristics for PCIe PHY (REFCLKP/N[2:0] and REFCLKP/N[2:0]).

Table 12-3 PCIe Reference Clock Requirement

Application	Reference Clock Jitter nd Swing Requirements
PCIe 1.1 – 2.5 GT/s	Refer to the PCI Express 3.0 Card Electromechamical specification.
PCIe 2.1 – 5.0 GT/s	Refer to the PCI Express 3.1 base specification.
PCIe 3.1 – 8.0 GT/s	Refer to the PCI Express 3.1 base specification.

12.4 INTEGRATED CLOCK BUFFER SPECIFICATIONS

The built-in Ingegrated Reference Clock Buffer of the PI7C9X3G606GP supports five reference clock outputs Table 12-4 Integrated Clock Buffer Output Electrical Characteristics specifies the voltage/timing requirements and operating characteristics for internal clock buffer outputs (REFCLKOP/N[7:4;1]).

$V_{TX-DIFF-PP-LOW}$	Low power differential p-p Tx voltage swing	0.4 (min) 1.2 (max)	0.4 (min) 1.2 (max)	See Table 12-6	VPP	As measured with compliance test load. Defined as $2*|V_{TXD+}-V_{TXD-}|$. See Note 9.
$V_{TX-DE-RATIO-3.5dB}$	Tx de-emphasis level ratio	3.0 (min) 4.0 (max)	3.0 (min) 4.0 (max)	See Table 12-6	dB	See PCI Express Base Specification Revision 3.1, Section 4.3.3.3 and Note 11.
$V_{TX-DE-RATIO-6dB}$	Tx de-emphasis lebel	N/A	5.5 (min) 6.5 (max)	See Table 12-6	dB	See PCI Express Base Specification Revision 3.1, Section 4.3.3.3 and Note 11.
$T_{MIN-PULSE}$	Instantaneous lone pulse width	Not specified	0.9 (min)	See Table 12-6	UI	Measured relative to rising/falling pulse. See Note 2, 10 and PCI Express Base Specification Revision 3.1, Figure 4-38.
T_{TX-EYE}	Transmitter Eye including all jitter sources	0.75 (min)	0.75 (min)	See Table 12-6	UI	Does not include SSC or Refclk jitter. Includes Rj at 10^{-12}. Note that 2.5 GT/s and 5.0 GT/s use different jitter determination methods.
$T_{TX-EYE-MEDIAN-to-MAX-JITTER}$	Maximum time between the jitter median and max deviation from the median	0.125 (max)	Not specified	Not specified	UI	Measured differentially at zero crossing points after applying the 2.5 GT/s clock recovery function. See Note 2.
$T_{TX-HF-DJ-DD}$	Tx deterministic jitter > 1.5 MHz	Not specified	0.15 (max)	See Table 12-6	UI	Deterministic jitter only. See Notes 2 and 10.
$T_{TX-LF-RMS}$	Tx RMS jitter < 1.5 MHz	Not specified	3.0	See Table 12-6	Ps RMS	Total energy measured over a 10 kHz - 1.5 MHz range.
$T_{RF-MISMATCH}$	Tx rise/fall mismatch	Not specified	0.1 (max)	Not specified	UI	Measured from 20% to 80% differentially. See Note 2.
$RL_{TX-DIFF}$	Tx package plus Si differential return loss	10 (min)	10 (min) for 0.05 -1.25 GHz 8 (min) for > 1.25 - 2.5 GHz	10 (min) for 0.05 -1.25 GHz 8 (min) for > 1.25 - 2.5 GHz 4 (min) for > 2.5 - 4 GHz	dB	For details refer to PCI Express Base Specification Revision 3.1, Figure 4-56.
RL_{TX-CM}	Tx package plus Si common mode return loss	6 (min) for 0.05 - 2.5 GHz	6 (min) for 0.05 - 2.5 GHz	6 (min) for 0.05 - 2.5GHz 3 (min) for 2.5 GHz	dB	For details refer to PCI Express Base Specification Revision 3.1, Figure 4-57.
$Z_{TX-DIFF-DC}$	DC differential Tx impedance	80 (min) 120 (max)	120 (max)	120 (max)	Ω	Low impedance defined during signaling. Parameter is captured for 5.0 GHz by $RL_{TX-DIFF}$. The (min) value is bounded by $RL_{TX-DIFF}$ for 5.0 GT/s and 8.0 GT/s.
$V_{TX-CM-AC-PP}$	Tx AC peak-peak common mode voltage (5.0 GT/s)	Not specified	150 (max)	150 (max)	mVPP	At 8.0 GT/s, no more than 50mVPP in 0.03-500 MHz range. At 5.0GT/s no more than 100mVPP in 0.03-500 MHz range. See Notes 5 and 12.
$V_{TX-CM-AC-P}$	Tx AC peak common mode voltage (2.5 GT/s)	20	Not specified	Not specified	mV	See Note 5.
$I_{TX-SHORT}$	Transmitter short-circuit current limit	90 (max)	90 (max)	90 (max)	mA	The total single-ended current a transmitter can supply when shorted to ground. See Note 13.
$V_{TX-DC-CM}$	Transmitter DC common-mode voltage	0 (min) 3.6 (max)	0 (min) 3.6 (max)	0 (min) 3.6 (max)	V	The allowed DC common-mode voltage at a transmitter pin under any conditions. See Note 13.
$V_{TX-CM-DC-ACTiVE-IDLE-DELTA}$	Absolute Delta of DC Common Mode Voltage during L0 and Electrical Idle	0 (min) 100 (max)	0 (min) 100 (max)	0 (min) 100 (max)	mV	$|V_{TX-CM-DC\ [during\ L0]} - V_{TX-CM-Idle-DC\ [during\ Electrical\ Idle]}| \leq 100mV$ $V_{TX-CM-DC} = DC_{(avg)}$ of $|V_{TX-D+} + V_{TX-D-}|/2$ $V_{TX-CM-Idle-DC} = DC_{(avg)}$ of $|V_{TX-D+} + V_{TX-D-}|/2$ [Electrical Idle]
$V_{TX-CM-DC-LINE-}$	Absolute Delta of	0 (min)	0 (min)	0 (min)	mV	$|V_{TX-CM-DC-D+\ [during\ L0]} - V_{TX-CM-DC-D-}$

DELTA	DC Common Mode Voltage between D+ and D-	25 (max)	25 (max)	25 (max)		$_{[during\,L0]}|\le 25mV$ $V_{TX-CM-DC-D+} = DC_{(avg)}$ of $|V_{TX-D+}|$ [during L0] $V_{TX-CM-DC-D-} = DC_{(avg)}$ of $|V_{TX-D-}|$ [during L0].
$V_{TX-IDLE-DIFF-AC-p}$	Electrical Idle Differential Peak Output Voltage	0 (min) 20 (max)	0 (min) 20 (max)	0 (min) 20 (max)	mV	$V_{TX-IDLE-DIFF-AC-p} = |V_{TX-Idle-D+} - V_{TX-Idle-D-}| \le 20mV$. Voltage must be band pass filtered to remove any DC component and HF noise. The bandpass is constructed from two first-order filters, the high pass and low pass 3dB bandwidths are 10 kHz and 1.25 GHz respectively.
$V_{TX-IDLE-DIFF-DC}$	DC Electrical Idle Differential Output Voltage	Not specified	0 (min) 5 (max)	0 (min) 5 (max)	mV	$V_{TX-IDLE-DIFF-DC} = |V_{TX-Idle-D+} - V_{TX-Idel-D-}| \le 5mV$. Voltage must be low pass filtered to remove any AC component. The low pass filter is first-order with a 3dB bandwidth of 10 kHz.
$V_{TX-RCV-DETECT}$	The amount of voltage change allowed during Receiver Detection	600 (max)	600 (max)	600 (max)	mV	The total amount of voltage change in a positive dirction that a Transmitter can apply to sense whether a low impedance Receiver is present. Note: Receivers display substantially different impedance for $V_{IN} < 0$ vs $V_{IN} > 0$. See PCI Express Base Specification Revision 3.1, Table 4-24 for detail
$T_{TX-IDLE-MIN}$	Minimum time spent in Electrical Idle	20 (min)	20 (min)	20 (min)	ns	Minimum time a Transmitter must be in Electrical Idle.
$T_{TX-IDLE-SET-TO-IDLE}$	Maximum time to transition to a valid Electrical Idle after sending an EIOS	8 (max)	8 (max)	8 (max)	ns	After sending the required number of EIOSs, the Transmitter must meet all Electrical Idel specifications within this time. This is measured from the end of the last UI of the last EIOS to the Transmitter in Electrical Idle.
$T_{TX-IDLE-TO-DIFF-DATA}$	Maximum time to transistion to valid diff signaling after leaving Electrical Idle	8 (max)	8 (max)	8 (max)	ns	Maximum time to transition to valid diff signaling after leaving Electrical Idle. This is considered a debounce time to the Tx.
$T_{CROSSLINK}$	Crosslink random timeout	1.0 (max)	1.0 (max)	1.0 (max)	ms	This random timeout helps resolve potential conflicts in the crosslink configuration.
$L_{TX-SKEW}$	Lane-to-Lane Output Skew	500 ps + 2 UI (max)	500 ps + 4 UI (max)	500 ps + 6 UI	ps	Between any two Lanes within a single Transmitter.
C_{TX}	AC Coupling Capacitor	75 (min) 265 (max)	75 (min) 265 (max)	176 (min) 265 (max)	nF	All Transmitters shall be AC coupled. The AC coupling is required wither within the media or within the transmitting component itself. See Note 14.

Note:
1. SSC permits a +0, -5000ppm modulation of the clock frequency ar a modulation rate not to exceed 33 kHz.
2. Measurements at 5.0 GT/s require an oscilloscope with a bandwidth of $\ge$12.5 GHz, or equivalent, while measurements made at 2.5 GT/s require a scope with a least 6.2 GHz bandwidth. Measurement at 5.0 GT/s must deconvolve effects of compliance test board to yield an effective measurement at Tx pins. 2.5 GT/s may be measured within 200 mils of Tx device's pins, although deconvolution is recommended. For measurement setup details, refer PCI Express Base Specification Revision 3.1, Figure 4-32 to and Figure 4-33. At lease 10^6 UI of data must be acquired.
3. Transmitter jitter is measured by driving the Transmitter under test with a low jitter "ideal" clock and connecting the DUT to a reference load.
4. Transmitter raw jitter data must be convolved with a filtering function that represents the worst case CDR tracking BW. 2.5 GT/s and 5.0 GT/s use different filter functions that are defined in PCI Express Base Specification Revision 3.1, Figure 4-49. After the convolution process has been applied, the center of the resulting eye must be determined and used as a reference point for obtaining eye voltage and margins.

5. $V_{TX-AC-CM-PP}$ and $V_{TX-AC-CM-P}$ are defined in PCI Express Base Specification Revision 3.1, Section 4.3.3.2. Measurement is made over at lease 10^6 UI.

6. The Tx PLL Bandwidth must lie between the min and max ranges given in the above table. PLL peaking must lie below the value listed above. Note: the PLL B/W extends from zero up to the values(s) specificied in the above table.

7. Measurements are made for both common mode and differential return loss. The DUT must be powered up and DC isolated, and its data+/data-output must be in the low-Z state at a static value.

8. A single combination of PLL BW and peaking is specified for 2.5 GT/s implementations. For 5.0 GT/s, two combinations of PLL BW and peaking are specified to permit designers to make a tradeoff between the two parameters. If the PLL's min BW is $\geq$ 8 MHz, then up to 3.0 dB of peaking is permitted. If the PLL's min BW is relaxed to $\geq$ 5.0 MHz, then a tighter peaking value of 1.0 dB must be met. In both cases, the max PLL BW is 16 MHz.

9. Reduced swing output, defined by $V_{TX-DIFF-PP-LOW}$ must be implemented as shown in PCI Express Base Specification Revision 3.1, Figure 4-37 with no de-emphasis.

10. For 5.0 GT/s, de-emphasis timing jitter must be removed. An additional HPF function must be applied as shown in PCI Express Base Specification Revision 3.1, Figure 4-49. This parameter is measured by accumulating a record length of 10^6 UI while the DUT outputs a compliance pattern. $T_{MIN-PULSE}$ is defined to be nominally 1 UI wide and is borderd on both sides by pulses of the opposite polarity. Refer to PCI Express Base Specification Revision 3.1, Figure 4-38.

11. Root Complex Tx de-emphasis is configured from Upstream controller. Downstream Tx de-emphasis is set via a command, issued at 2.5 GT/s. For detail, refer to the appropriate location in PCI Express Base Specification Revision 3.1, Section 4.2.

12. Tx CM noise for 8.0 GT/s is measured at TP1 without de-embedding the breakout channel. The parameter captures device CM noise only and is not intended to capture system CM noise. For 5.0 GT/s an LPF with a -3 dB corner at 2.5 GHz is applied to the raw data. For 8.0 GT/s the filter's -3 dB corner is at 4.0 GHz.

13. $I_{TX-SHORT}$ and $V_{TX-DC-CM}$ stipulate the maximum current/voltage levels that a transmitter can generate and therefore define the worst case transients that a receiver must tolerate.

14. All platforms that have transmitters supporting 8.0 GT/s must implement the 176-265 nF C_{TX} value. Platforms operating at 2.5 or 5.0 GT/s only may implement over a range of 75 to 265 nF.

Table 12-6 8.0 GT/s Specific Tx Voltage and Jitter Parameters

Symbol	Parameter	Value	Units	Notes
$V_{TX-FS-NO-EQ}$	Full swing Tx voltage with no TxEq	1300 (max) 800 (min)	mVPP	See Note 1.
$V_{TX-RS-NO-EQ}$	Reduced swing Tx voltage with no TxEq	1300 (max)	mVPP	See Note 1.
$V_{TX-EIEOS-FS}$	Min swing during EIEOS for full swing	250 (min)	mVPP	See Note 2.
$V_{TX-EIEOS-RS}$	Min swing during EIEOS for reduced swing	232 (min)	mVPP	See Note 2.
T_{TX-UTJ}	Tx uncorrelated total jitter	31.25 (max)	Ps PP @ 10^{-12}	
$T_{TX-UDJDD}$	Tx uncorrelated deterministic jitter	12 (max)	Ps PP	
$T_{TX-UPW-TJ}$	Total uncorrelated PWJ	24 (max)	Ps PP @ 10^{-12}	See Notes 3 and 4.
$T_{TX-UPW-DJDD}$	Deterministic DjDD uncorrelated PWJ	10 (max)	Ps PP	See Notes 3 and 4.
T_{TX-DDJ}	Data dependent jitter	18 (max)	Ps PP	See Notes 4 and 5.
$Ps21_{TX}$	Pseudo package loss	-3.0 (min)	dB	PP ratio of 64 ones/64 zeroes pattern vs. 0101 pattern. No Tx equalization. See Note 6.
$V_{TX-BOOST-FS}$	Tx boost ratio for full swing	8.0 (min)	dB	Assumes ±1.5 dB tolerance from diagonal elements in PCI Express Base Specification Revision 3.1, Figure 4-45.
$V_{TX-BOOST-RS}$	Tx boost ratio for reduced swing	2.5 (min)	dB	Assumes ±1.0 dB tolerance from diagonal elements in PCI Express Base Specification Revision 3.1, Figure 4-45.
$EQ_{TX-COEFF-RES}$	Tx coefficient resolution	1/24 (max) 1/63 (min)	N/A	

Note:

1. Voltage measurements for $V_{TX-FS-NO-EQ}$ and $V_{TX-RS-NO-EQ}$ are made using the 64-zeroes/64-ones pattern in the compliance pattern.

2. Voltage limits comprehand both full swing and reduced swing modes. The Tx must reject any changes that would violate this specification. The maximum level is covered in the $V_{TX-FS-NO-EQ}$ measurement which represents the maximum peak voltage the Tx can drive. The $V_{TX-EIEOS-FS}$ and $V_{TX-EIEOS-RS}$ voltage limits are imposed to guarantee the EIEOS threshold of 175 mVPP at the Rx pin. This parameter is measured using the actual EIEOS pattern that is part of the compliance pattern and then removing the ISI contribution of the breakout channel. The transmitter must advertise a value for LF during TS1 at 8.0 GT/s that ensures that these parameters are met.

3. PWJ parameters shall be measured after DDJ separation.

4. Measured with optimized preset value after de-embedding to Tx pin.

5. The 18 ps number takes into account measurement error.

6. The -3.0 dB number takes into account measurement error. For some Tx package/driver combinations ps21$_{TX}$ may be greater than 0 dB.

Symbol	Parameter	2.5 GT/s	5.0 GT/s	8.0GT/s	Units	Comments
RL$_{RX-CM}$	Common mode Rx return loss	6 (min)	6 (min)	6 (min) for 0.05 -2.5 GHz 5 (min) for > 2.5 - 4.0 GHz	dB	See PCI Express Base Specification Revision 3.1, Figure 4-60 and Note 4.
Z$_{RX-DC}$	Receiver DC single ended impedance	40 (min) 60 (max)	40 (min) 60 (max)	Not specified	Ω	DC impedance limits are needed to guarantee Receiver detect. For 8.0 GT/s is bounded by RL$_{RX-CM}$. See Note 5.
T$_{RX-GND\_FLOAT}$	Rx termination ground float time	Not specified	Not specified	500	µs	Time allowed to float Rx internal ground in 2.5 GT/s/ 5.0 GT/s to 8.0 GT/s configuration change. See Note 8.
Z$_{RX-DIFF-DC}$	DC differenital impedance	80 (min) 120 (max)	Not specified	Not specified	Ω	For 5.0 GT/s and 8.0 GT/s coverd under the RL$_{RX-DIFF}$ parameter. See Note 5.
V$_{RX-CM-AC-P}$	Rx AC common mode voltage	150 (max)	150 (max)	75 mV (max) (EH < 100 mVPP) 125 mV (max) (EH < 100 mVPP). See Table 12-10	mVP	Measured at Rx pins into a pair of 50 Ω terminations into ground. See Not 6.
Z$_{RX-HIGH-IMP-DC-POS}$	DC input CM Input Impedance for V > 0 during Reset or power down	≥10 k or ≥20 k	≥10 k or ≥20 k	≥10 k or ≥20 k	Ω	Rx DC CM impedance with the RX terminations not pwered. ≥10 kΩ over 0-200 mV range wrt. Ground and ≥20 kΩ for voltages ≥200 mV wrt ground. See Note 9.
Z$_{RX-HIGH-IMP-DC-NEG}$	DC input CM input Impedance for V < 0 during Reset or power down	1.0 k (min)	1.0 k (min)	1.0 k (min)	Ω	Rx DC CM impedance with the Rx terminations not powered, measured over the range -150 to 0 mV with respect to ground. See Note 7.
V$_{RX-IDLE-DET-DIFFp-p}$	Electrical Idle Detect Threshold	65 (min) 175 (max)	65 (min) 175 (max)	65 (min) 175 (max)	mV	V$_{RX-IDLE-DET-DIFFp-p}$ = 2*|V$_{RX-D+}$ - V$_{RX-D-}$|. Measured at the package pins of the Receiver. See PCI Express Base Specification Revision 3.1, Section 4.2.4.3.
T$_{RX-IDLE-DET-DIFF-ENTERTIME}$	Unexpected Electrical Idle Enter Detect Threshold Integration Time	10 (max)	10 (max)	10 (max)	ms	An unexpected Electrical Idle (V$_{RX-DIFF-PP}$ < V$_{RX-IDLE-DET-DIFFp-p}$) must be recognized on longer than T$_{RX-IDLE-DET-DIFF-ENTERTIME}$ to signal an unexpected idle condition.
L$_{RX-SKEW}$	Lane to Lane skew	20 (max)	8 (max)	6 (max)	ns	Across all Lanes on a Ports. L$_{RX-SKEW}$ comprehends Lane-Lane variations due to channel and repeater delay differences.

Note:
1. Receiver eye margins are defined into a 2x 50 Ω reference load.
2. The four inherent timing error parameters are defined for the convenience of Rx designers, and they are measured during Receiver tolerancing.
3. Two combinations of PLL BW and peaking are specified at ≥5.0 GT/s to permit designers to make tradeoffs vetween the two parameters. If the PLL's min BW is ≥8 MHz, then up to 3.0 dB of peaking is permitted. If the PLL's min BW is relaxed to ≥5.0MHz, then a tighter peaking value of 1.0 dB must be met. Note: a PLL BW extends from zero up to value(s) defined as the min or max in the above table. For 2.5 GT/s a single PLL bandwidth and peaking value of 1.5-22 Mhz and 3.0 dB are defined.
4. Measurements must be made for both common mode and differential return loss. In both cases the DUT must be powered up and DC isloated, and its D+/D- inputs must be in the low-Z state.
5. The Rx DC single ended impedance must be present when the Receiver terminations are first enabled to ensure that the Receiver Detect occurs properly. Compensation of this impedance can start immediately and and the Rx Common Mode Impedance (Constrained by RL$_{RX-CM}$ to 50 Ω ±20%) must be within the specified range by the time Detect is entered.
6. Common mode peak voltage is defined by the expression: max{\|(V$_{D+}$-V$_{D-}$) − V$_{-CMDC}$\|}.
7. Z$_{RX-HIGH-IMP-DC-NEG}$ and Z$_{RX-HIGH-IMP-DC-POS}$ are defined respectively for negative and positive voltages at the input of the Receiver. Transmitter designers need to comprehend the large difference between >0 and <0 Rx impedances when designing Receiver detect circuits.

2. Accumulated over 10^6 UI.

3. Minimum eye is obtained by first injecting maximum Dj and then adjusting Rj until a minimum eye (defined by T_{RX_EYE} as show in PCI Express Base Specification Revision 3.1, Figure 4-63) is reached. Rj is spectrally flat before being filtered with a BPF having 3 dB cut-offs f_{C_LOW} and f_{C-HIGH} of 1.5 MHz and 100 MHz, rspectively with step rolloff at 1.5 MHz and a 20 dB/decade rolloff on the high side. Minimum eye width is defined for a sample size equivalent to a BER of 10^{-12}.

4. Different combinations of $T_{RX-HF-DJ-DD}$ and $T_{RX-HF-RMS}$ are needed to measure $T_{RX-TJ-CC}$ and $T_{RX-DJ-DD-CC}$.

Table 12-9 5.0 GT/s Tolerancing Limits for Data Clocked Rx Architecture

Parameter	Description	Min	Max	Units	Notes
UI	Unit interval without including of SSC	199.94	200.06	ps	Over 10^6 UI
$T_{RX-HF-RMS}$	1.5 – 100 MHz RMS jitter		4.2	ps RMS	Spectrally flat, see Note 3
$T_{RX-HF-DJ-DD}$	Max Dj impinging on Rx under test		88	ps	See Notes 2 and 4
$T_{RX-SSC-RES}$	33 kHz Refclk residual		20	ps	
$T_{RX-LF-RMS}$	< 1.5 MHz RMS jitter		8.0	ps RMS	Spectrally flat
$T_{RX-MIN-PULSE}$	Minimum single pulse applied at Rx	120		ps	See Note 2
$V_{RX-MIN-MAX-RATIO}$	Min/max pulse voltage ratio seen over an time interval of 2 UI		5		See Note 2
V_{RX-EYE}	Receive eye voltage opening	120		mVPP diff	See Notes 1 and 3
$V_{RX-CM-CH-SRC}$	Common mode noise from Rx		300	mVPP	See Note 2

Note:
1. Refer to PCI Express Base Specification Revision 3.1, Figure 4-63 for a description of how the Rx eye voltage is defined.

2. Accumulated over 10^6 UI.

3. Minimum eye is obtained by first injecting maximum Dj and then adjusting Rj until a minimum eye (defined by T_{RX_EYE} as show in PCI Express Base Specification Revision 3.1, Figure 4-63) is reached. Rj is spectrally flat before being filtered with a BPF having 3 dB cut-offs f_{C_LOW} and f_{C-HIGH} of 1.5 MHz and 100 MHz, rspectively with step rolloff at 1.5 MHz and a 20 dB/decade rolloff on the high side. Minimum eye width is defined for a sample size equivalent to a BER of 10^{-12}.

4. Different combinations of $T_{RX-HF-DJ-DD}$ and $T_{RX-HF-RMS}$ are needed to measure $T_{RX-TJ-CC}$ and $T_{RX-DJ-DD-CC}$.

Table 12-10 Stressed Voltage Eye Parameters

Symbol	Parameter	Limits at 8.0GT/s	Units	Comments
$V_{RX-LAUNCH-8G}$	Generator launch voltage	800	mVPP	Measured at TP1. Please refer to PCI Express Base Specification Revision 3.1, Figures 4-65. $V_{RX-LAUNCH-8G}$ may be adjusted if necessary to yield the proper EH as long as the outside eye voltage at TP2 does not exceed 1300 mVPP.
$T_{RX-UI-8G}$	Unit Interval	125.00	ps	Nominal value is sufficient for Rx tolerancing. Value does not account for SSC.
$V_{RX-SV-8G}$	Eye height at TP2P	25 (-20 dB channel) 50 (-12 dB channel) 200 (-3 dB channel)	mVPP	Eye height @ BER = 10^{-12}. See Notes 1 and 2.
$T_{RX-SV-8G}$	Eye width at TP2P	0.3 to 0.35	UI	Eye width at BER = 10^{-12}. See Note 2.
$V_{RX-SV-DIFF-8G}$	Differential mode interference	14 or greater	mVPP	Adjusted to set EH/ Frequency = 2.10

				GHz. See Note 3.
$V_{RX-SV-CM-8G}$	Rx AC Common mode voltage at TP2P	150 (EH < 100 mVPP) 250 (EH ≥ 100 mVPP)	mVPP	Defined for a single tone at 120 MHz. See Note 3.
$T_{RX-SV-SJ-8G}$	Sinusoidal Jitter at 100 MHz	0.1	UI PP	Fixed at 100 MHz. See Note 4.
$T_{RX-SV-RJ-8G}$	Random Jitter	2.0	Ps RMS	Rj spectrally flat before filtering. See Notes 4 and 5.
$V_{RX-MAX-SE-SW}$	Max single-ended swing	±300	mVP	See Note 6.

Note:

1. $V_{RX-SV-8G}$ is tested at three different voltages to ensure the Rx DUT is capable of equalizing over range of channel loss profiles. The test also guarantees the Rx is capable of operating over a sufficient dunamic range of eye heights. This "SV" in the parameter names refers to stressed voltage.

2. $V_{RX-ST-8G}$ and $T_{RX-ST-8G}$ are referenced to TP2P and are obtained after post processing data captured at TP2.
   $V_{RX-ST-8G}$ and $T_{RX-ST-8G}$ include the effects of applying the behavioral Rx model and Rx behavioral equalization.

3. $V_{RX-SV-DIFF-8G}$ measurement is made at TP2 without post processing. $V_{RX-SV-CM-8G}$ may be made at either TP1 or TP2. $V_{RX-SV-DIFF-8G}$ voltage may need to be adjusted over a wide range for the different loss calibration channels.

4. $T_{RX-SV-SJ-8G}$ and $T_{RX-SV-RJ-8G}$ measurements are made at TP1 without post processing.

5. Rj is applied over the following range. The low frequency limit may be between 1.5 and 10 MHz, and the upper limit is 1.0GHz. See PCI Express Base Specification Revision 3.1, Figure 4-47 for details.

6. $V_{RX-MAX-SE-SW}$ sets the maximum outer, single-ended eye voltage limit in the presence of differential and CM noise applied to the Rx, as observed at TP2 relative to ground with no behvioral RxEq post processing.

Table 12-11 Stressed Jitter Eye Parameters

Symbol	Parameter	Limits at 8.0GT/s	Units	Comments
$V_{RX-LAUNCH-8G}$	Generator launch voltage	800 (nominal)	mVPP	Measured at TP1, See PCI Express Base Specification Revision 3.1, Figure 4-65 and Note 1.
$T_{RX-UI-8G}$	Unit Interval	125.00	ps	Nominal value is suffivient for Rx tolerancing. Value does not account for SSC.
$V_{RX-ST-8G}$	Eye height at TP2P	25 (min) 35 (max)	mVPP	At BER = 10^{-12}. See Note 2.
$T_{RX-ST-8G}$	Eye width at TP2P	0.30	UI	At BER = 10^{-12}. See Note 2.
$T_{RX-ST-SJ-8G}$	Sinusoidal Jitter	0.1 - 1.0	UI PP	See PCI Express Base Specification Revision 3.1, Figure 4-74 Measured at TP1. See Note 3.
$T_{RX-ST-RJ-8G}$	Random Jitter	3.0	ps RMS	Rj spectrally flat before filtering. Measured at TP1, See Note 4.

Note:

1. $V_{RX-SV-8G}$ may be adjusted to meet $V_{RX-ST-8G}$ as long as the outside eye voltage at TP2 does not exceed 1300 mVPP.

2. $V_{RX-ST-8G}$ and $T_{RX-ST-8G}$ are referenced to TP2P and are obtained after post processing data captured at TP2.
   $V_{RX-ST-8G}$ and $T_{RX-ST-8G}$ include the effects of applying the behavioral Rx model and Rx behavioral equalization.

3. $T_{RX-ST-SJ-8G}$ may be measured at either TP1 or TP2.

4. While the nominal value is specified at 3.0 ps RMS, it may be adjusted to meet the 0.3 UI value for $T_{RX-ST-8G}$. Rj is measured at TP1 to prevent data-channel interaction from adversely affecting the accuracuy of the Rj calibration.

   Rj is applied over the following range. The low frequency limit may be between 1.5 and 10 MHz, and the upper limit is 1.0 GHz.
